Seeing then that specialism has had such mixed origins, we may well inquire whether it is altogether a good thing. Up to a point it obviously is. But it has in parts gone beyond that point. The one-eyed specialist comes to be too much interested in his disease or his operation, too little in his patient. The cardiologist must diagnose some cardiac disease or nothing at all. There are cases of bronchiectasis lying about undiagnosed in sanatoria because the tuberculosis specialists have forgotten every other disease except tuberculosis. The too narrow specialist gets bored with his job because it is too monotonous, and no-one can do a job well who is bored with it. How much can a school medical officer do for school-children whom he examines only three times or so in their school career, when he never sees them in their homes, never gets to know their parents, never follows the course of disease in children either in their homes or in a hospital? The nature of his job, one would think, must lead to atrophy of his medical mind; little wonder that he sometimes comes to consider that every tonsil bigger than its owner's marbles should be guillotined. The narrow specialist gets narrower still if he works in a special building, away from his colleagues in other fields of medicine, never consulting with them over problems of sickness or health, never learning from them or having his mind criticised and cross-fertilised by theirs. Those are some of the ill results of specialism, which strongly suggest that, necessary as it is, it has in places gone too far. Another weakness is that it has robbed the general practitioner of much work that he can do quite well, or at least could do well if he had better conditions in which to work and closer contact with the real experts in the special fields who could guide and advise him without extra cost to his patient.

Turn now to specialism in medical education. What a way we have come since the days when the medical student apprenticed himself to a doctor in practice and learnt his job, haphazard but practically, from his master. Look at our modern curriculum—a great agglomeration and conglutination of subjects each in an almost water-tight shell. We are trying to feed the embryo doctor through a placenta made of stratified cornified epithelium instead of through a living syncytium. Each subject is necessary, of course, and each subject is developed and taught much better by its specialists than it could be by any jack-of-all-trades; but the specialists tend to teach their subjects, instead of teaching their students. At every curriculum-casting committee in every university you will find every professor urging the great importance of his own subject, fighting for more time to be given to it. It is really very noble of them, for the more time every professor gets the more work he has to do, at the same salary; there is that surprising touch of nobility about professors which you may not appreciate. But if I were the principal of a university presiding over the curriculum-makers, I should say to the anatomist "Now, you go out into the quadrangle while the rest of us decide how much time the student should spend on anatomy." Then ditto to the physiologist, for physiology; and ditto for materia medica, pathology, public health and all the rest of them, with the possible exception of the subject of medicine; there I'd have a few good practitioners in to make sure that the student has plenty of time for practical experience of patients, both at hospital and sometimes in their homes. If we went on in the same way to decide what to teach as well as how much to teach we might achieve a reasonably coördinated compassable curriculum. That way or some other we shall, I am sure, alter the curriculum, and I hope we shall go on altering it, for medicine is a living thing, and all living things must grow and change, adapting themselves to their changing environment. "What was good enough for our fathers is good enough for us" is the motto of the dinosaur and the dodo.

MEDICINE IN A CHANGING SOCIETY

The social environment of medicine in our country is changing fast. Last century was the heyday of free-trade: buy in the cheapest market, sell in the dearest; never mind who suffers, so long as the dividends are high; fight with your competitors, undersell them, buy them up; judge your success by your balance-sheet. Those were the orders of the day, and they worked pretty well for a time. But when international competition pressed hard on us, when slumps came, the ruthlessness of unrestrained commercialism gave us our millions of unemployed and our cancerous depressed areas Under that system we distributed the profits of trade unequally, and the losses with cruel unfairness But at the same time the notion was growing that services rendered are more important than profits gained In a few enterprises the people as a whole took charge, through Parliament or local authorities, in the hope that they would get better value and fairer distribution than competing private firms could give them The Post Office was one of the earliest examples Education was another with few exceptions, schools and universities are run by the people through their representatives, and their aim is to get good teaching, not to make big profits either for teachers or governors Many electricity and gas undertakings are now owned and managed on the same principle, so are the BBC and some parts of the nation's transport organisation Then the war came, and in an astonishingly short time the whole of industry and the bulk of commerce have come under direct government control

---

[1] Presidential address to the Students' Medical Society of the University of Aberdeen, May 19, 1942.

6209

In war the needs and the safety of all of the people are obviously paramount, for if one section of them is allowed to go hungry or unprotected the whole population is jeopardised, so commercial competition has been whittled down to next to nothing, for nation-wide safety and nation-wide security can be achieved only through nation-wide organisation, planned for the people's benefit When peace comes that lesson will not be forgotten, and in many activities national control in some form will persist Call it socialism if you like—it is not a revolution, or a political label, but just a change in social structure that has been coming gradually for half a century and is now coming much faster under the impetus of war Its causes lie deeper than political parties Since it is fundamentally due to the impact of applied science on human life it is an inevitable change and there is no sense in opposing it But there is every need to mould the form and direction it takes, for this may be either the National Socialism of the German totalitarian type (" the squalid hell of the totalitarian ant-heap ") or the democratic variety that we are feeling after

Now medicine has had much in common with commerce A doctor's services were his stock-in-trade which he sold to the highest bidder He would always prefer a practice in a good-class area to one in a poor area, if he thought he could make it He would often be jealous and unfriendly towards his fellow practitioners in the town, he might say to himself that this was because they were incompetent unscrupulous cads, but the basic reason was that they were his competitors He could hardly help giving more time and attention to his private patients who paid fees than to his panel patients He could hardly help being more interested in Johnnie Anderson's acute appendicitis, which called for a dramatic and expensive operation, than in Tommie Davidson's nocturnal enuresis, which required a series of interviews with Tommie's terrifying mother His work was often good and it no doubt owed much to the stimulus of fees and competition, but in many ways it was hindered by the fact that he was selling his medicine in the market, not giving it to those who most needed it True there was the praiseworthy Robin Hood system whereby the specialist served the poor in the hospitals for nothing while he mulcted the rich in maximum fees, but that is rapidly dying because there are more and more specialists needed and fewer and fewer rich to support them Tomorrow the same principle will come to be applied to medicine as to education a nation-wide organisation aimed at nation-wide service, free from commercial competition And this principle will be applied not by the doctors but by the people, just as was the National Health Insurance of 1911 We shall spare ourselves a lot of useless thought and futile words if we see that clearly Irresistible social and economic forces—the demand of an educated people for the benefits medical science can give them—will bring about a nation-wide organisation of the medical profession, and the elimination of commercial competition between doctors Do we sit back dumb, and just wait till it comes? No Organisation must come, but it is in our power as a profession to design that organisation, and it is immensely important that we should design it well

WHAT SHALL WE KEEP?

Two tenets of the medical tradition belong to the very heart of it, and have contributed much to the nobility of our profession at its best, these we must struggle to preserve in the new organisation The first is that medicine gives highest place to the value of the human individual, not to the factory or the town or the state Whether the patient is a great scientist, a leader in politics or a humble rather stupid labourer, a good doctor will do his best for him We build better hospitals for the poor than for the rich, we take trouble to patch up the cripples, and ease the sufferings of people with incurable diseases, regardless of their economic uselessness Who knows better than the doctor that every mother's baby is supremely important to her, though only a cipher to the Registrar-General? The aim of our labours is the health and happiness of our individual fellow men, and we are coming to include in that their mental and spiritual health as well as their bodily health For that reason we set much store by what we call the doctor-patient relationship Every patient is different from every other, and the doctor who wishes to guide a patient towards better health must know him personally and know him well The individual, however, is not an independent unit, his health and happiness are greatly affected by his ties with his fellow-men Indeed if you turn philosophical in a simple way and ask yourself wherein human happiness lies, you can't say much more than this a man is happy in his work and in the human relationships he achieves with his family and his fellows provided he develops his best powers to their fullest in those two spheres The doctor's task is to help individual people to that enjoyment and employment of their own powers This emphasis on the importance of the individual is not peculiar to medicine It is fundamental in the Christian religion, especially in the protestant forms of it And it is of the essence of democracy "We hold these truths to be self-evident," runs the Declaration of American Independence, "that all men are created equal, that they are endowed by their Creator with certain inalienable rights, that among these are life, liberty and the pursuit of happiness" The medical view, the religious view and the democratic view are all essentially the same

The second principle in the medical tradition is really an application of the first to the doctor himself It is that the doctor should have liberty He should be free to seek the job in medicine that draws the best out of him, to put his best in the way of effort and enterprise into his work His liberty, like all democratic liberty, should be limited only by the one restriction—that his exercise of it shall not do wanton harm to someone else Apart from that he should have scope enough and responsibility enough to develop his own powers to his utmost

HOW SHALL WE KEEP IT?

The future organisation of medicine can do much to destroy, or to preserve, those two principles A service based on the old-fashioned Army model, where orders and regulations emanate from headquarters, and for all below the rank of general the rule is "theirs not to reason why, theirs but to do or die," is one possibility It could be made to work like a beautifully designed machine, or an automatic telephone exchange, but it would be blind to the individuality of patients, and would tend to treat all those bearing the same diagnostic label in exactly the same way Many of the doctors working in it would flag in their interest, and lose their drive; the rules would check their initiative and hinder their development, and standardise medicine into the semblance of Woolworth's stores We should hate that, and medicine would become a poor thing

Can we picture an alternative, where within the frame work of a nation-wide organisation and under efficient general direction doctors can keep their true liberty and the welfare of the individual patient can remain the guiding aim? The model I suggest is the mammalian body, whose ways of working we know a little about It has central direction, in the brain, but that brain is the focus of constant impulses streaming in from the whole body—information about the outside world, its opportunities and its dangers, news about this and demands for that from the body's various parts Indeed when all these afferent impulses are cut off the cerebral cortex ceases to function and goes to sleep. But even when functioning the brain leaves a lot to the common sense and enterprise of the various parts of the body. The heart, the kidneys, the liver and many other glands are semi-independent; they can vary their activity a great deal to meet changing needs, without reference to the brain. Even the bladder, when cut off from the brain in paraplegia, can run its own show—or should I say pump its own ship? That is what the physiologists call an integrated organism. Every little part has its job to do, its own share of responsibility and independence, and its own voice in the management of the whole concern. It is an excellent model for the future medical organisation in which we want the individual doctors, and the little groups of doctors working in group practices, in hospitals, in local health services, to have the maximum possible of responsibility, both for their own work, and for the policy of the institutions in which they work, all under a tolerant and stimulating general direction.

TRAINING OURSELVES

This is not the place to discuss the detailed anatomy of such a medical service. Planners in plenty are already occupied with that and all whose motives are disinterested should be encouraged. Here however we might usefully ask what qualifications you and I need if we are to play our part as individual cells in the new organism. I take for granted reasonable intelligence and those northern virtues of honesty, hard work and so on which are carried on the same chromosome as an addiction to porridge and a true appreciation of whisky, and I propose in addition three qualities that we need to cultivate in ourselves.

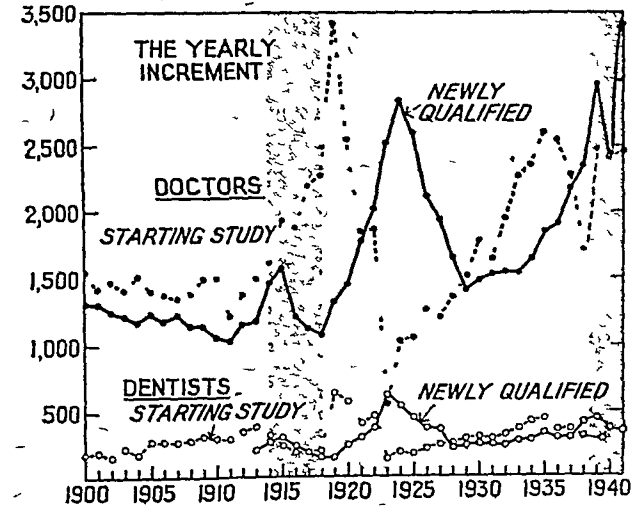
The first is the faculty of getting on with people. We all know and value the social aspect of this faculty but it also has its bearing on work. Some people cooperate much better than others, in getting a job of work done by a team. Cooperation means working with, and it isn't always easy, for the other people are so often fools, or lazy, or distasteful to us. Our medical training as students doesn't give us much practice in cooperative tasks; in hearing lectures, studying books, sitting examinations it is every man for himself. Only when we become residents do we find ourselves one of a group of people concentrating on a joint task, and even then the division of labour among chief, houseman, sister and nurses is so sharp that each of us feels still very much on his own. In other student activities, however, we do see some joint effort, which has to be planned and carried through by groups of people working together. Every student club and society is an example, except where the committee leaves everything to the poor dog of a secretary. But we need *much more training* than we get in the technique of sharing a job with other people, and in the technique of joint thinking and planning, which is what most committees are supposed to do. Medical men are often bad committee men, and that is a pity, for committees, small and large, are essential to our integrated democratic medical organisation. They are like the peripheral ganglia of the autonomic nervous system. The procedure of a committee should run like this: (1) collect the facts; (2) hear the views of everybody; (3) discuss those views with the object of evolving a joint opinion, or at worst, a majority opinion; (4) take action on that joint opinion. The faults arise in (3) and (4), forgetting that the object is to evolve a joint opinion, people indulge in dog-fights or go off on irrelevant reconnaissances which waste time. When it comes to taking action, those who didn't approve of the action decided on must still do their best to carry it out, unless they feel strongly enough to resign. I believe that we need to study and practise the technique of working in groups and thinking in groups if we are to make a success of the medicine of tomorrow. There is going to be little room for the lone hand. I know the lone hand is occasionally a genius; in that case we should be tolerant and indulge him, give him his head and his opportunity, not insist on his obeying every rule and regulation that we have imposed on ourselves. But much more often the lone hand is just a capable enough man, with an excessive share of selfishness and obstinacy, and he is more nuisance than he's worth.

The second quality we must encourage in ourselves is enterprise and ingenuity. Medicine is a living growing developing thing, and changes fast. If we limit ourselves to learning what the last generation had to teach us and carrying that out, we are a drag on its advancement. That was medieval medicine, in which the last word was Galen; it should have died with Harvey, but the dodos are still among us. We should blot their motto out and put up instead, "There must be a better way of doing this: what is it? Let's try something." A restless desire for improvement is a real necessity, and the way to improve is to think a little and then to experiment. Surely there are better ways of studying medicine, of teaching medicine, of running a ward. We should be enterprising and ingenious in our own small spheres now, and we should carry that impulse to continuous improvement into our new organisation when it comes, whether we are to have big jobs in it or little ones.

Thirdly, I think we need something in the nature of an ideal to hold in front of us. The word "idealist" has acquired a faint flavour of scorn, at least on the lips of the hard-boiled "realist," who is convinced that what he knows of life is all anyone knows or needs to know. Ideals too, blossom best in the minds of youth, at a stage in life when the means of realising them are not to hand. The middle-aged and the elderly—an increasing proportion of the population—impressed by their own success or cynical from their own disillusionment, often rate experience as of more value than ideals, and apply damp cloths to the ardent brow of youth. Now I wonder whether that has been happening too much in our country, for great achievements in human life are to be realised only by the process of putting faith in an ideal and working for it. There are two incentives that will make a donkey move—a carrot before his nose, or a goad stuck into his rump—and you and I know that we make our best and most effective effort when we are all out after a juicy carrot, not when we are reluctantly spurred by the goad. I look at the immense achievement of Germany, in preparing and launching this war; its power came from the ideal of world domination dangled before the eyes of German youth. A foul and rotten carrot, it is true, but it produced a mighty effort. I look at the even greater achievement of Russia, in organising 170 million people into a modern industrial state within a decade or two. The ideal there was the application of modern science to developing the material resources of a rich neglected country. The youth of Russia had faith in their ideal, even to the dangerous extent of talking about it, and they have not only achieved the greater part of their object, but have also put themselves, in the bygoing, into the same military class as Germany. What ideal was stirring the hearts and stimulating the effort of our British youth before the war? I am afraid the answer is, hardly any. I am afraid we mostly drifted or meandered along well-worn traditional paths until we were suddenly face to face with impending calamity. Shall we resume our drifting after the war? If we do the calamity will not only impend next time but will befall us. The war is hardly worth fighting unless we are going to enrich the peace that follows with a new and vigorous effort after something worth while, something better than we've had before. That is true in medicine as much as in national life, and in medicine the ideal is not far to seek. It is to secure better health, physical and mental, for every man, woman and child in the country. Set that up as your ideal; remember our belief that the individual is the most important unit, and that every individual differs from every other, and you will be doing something far better than human stud-farming aimed at industrial or military efficiency.

Begin with the individual, as the doctor should, and you will soon find how intimately he is related to his family and community. Study the effect of that on his health and you will come up against all sorts of problems waiting to be tackled. If you conclude, for example, that good mental health is rooted in good family relationships, you will agree that the general practitioner should be a family doctor. You will ask what size of family is best, and you will probably decide that father, mother and four children is about the minimum, because, well managed, that provides a rich and varied pattern of relationships for its members to live through. Then you will inquire whether society makes it possible, or not too difficult, for parents to have four or more children, and manage their families well If not, why not? You will look at the ageing and the old members of the community You will see how devastating it is, to their health, when the community casts them off, leaves them with no job of work to do, but with only a depressing sense of senescent futility You will ask why society doesn't reorganise the work that has to be done, in such a way as to give the old people a share in it suited to their powers —jobs that are not too big, lest they exhaust themselves or wield too great an influence as brakes on progress, but jobs that will make use of their wisdom and their remaining capacity, preserve their self-respect, and literally keep them longer alive Among the younger people you will often wonder whether so-and-so's job is the one that he is best suited for, and you will ask whether ways and means can't be found for avoiding occupational misfits and setting the square pegs into square holes You know already how we are up against the problems of nutrition and housing, how inadequate food and overcrowding make millions of people fall short of their best in the way of health In all these and many other ways, if you seek as your ideal the better health of every single individual, you will find a task that is big enough and worth while enough to call forth all the brain, enterprise, sympathy and powers of work that you possess You will also encounter social, economic, and political difficulties that you alone are powerless to overcome, you alone can do nothing to relieve poverty, nothing to improve education; you will feel helpless and almost hopeless, and you may be tempted to fall back dispirited on bottles-of-medicine treatment, and the feeble palliation of preventable ill health But supposing the whole medical profession could make up its mind on any one of these wider problems and tell the country with a united voice and with fifty thousand separate voices just what ought to be done, would that be without effect? By no means. If we had an integrated medical profession, loyal and pulling together, we could exert an undreamt of influence for good in politics and economics We could have diphtheria immunisation made universal in a year, and tubercle bacilli banished from the milk in very little longer "Idealism!" you say mockingly, "you'll never get doctors to work together like that" Why not try?

THE NUMBERS WHO ENTER THE MEDICAL PROFESSION



Changes in the Curriculum

TEACHERS INTERVIEWED

How would you teach the medical student to relate chemistry to pharmacy and to metabolism?—The relationship of chemistry to pharmacy is, I think, best dealt with by having a course of pharmacology in which drugs are considered from the point of view of their mode of action, and chemical structure is only discussed on broad principles, especially where it is related to mode of action In addition, some relationship between chemistry and pharmacy can be shown in the course of practical pharmacy, for example when discussing incompatibles The relationship of chemistry to metabolism is best taught by coordinating courses throughout the medical curriculum Misunderstandings commonly arise because of lack of coordination between the teachers of chemistry in the first year, biochemistry in the second and third years, physiology, and so-called pathological chemistry and the clinical aspects of metabolic disorder during the later years These various aspects of chemistry in relation to metabolism can best be made clear to the student in the physiology department

How could you bring back into wedlock those divorced subjects, human structure and function?—One of the most retrogressive changes in recent years has been the shifting of histology from physiology to anatomy departments In the past it was the practice to teach microscopic structure in relation to function, and this is obviously most properly and competently done in a physiology department Many modern anatomists are well able, and indeed anxious, to stress function rather than structure, but it is doubtful whether in practice the average anatomist is in a position to deal adequately with the functional side of the question Then undue stress is laid on morbid anatomy by pathologists, to the exclusion of abnormal function The Oxford school have done much to promote experimental pathology and the investigation of the functional errors in disease, but elsewhere the old type of morbid anatomy still prevails

How would you light in the student the impulse to keep abreast of advances in therapy?—Scientific societies at which papers can be read and discussed helps to interest the student in progress Much can be done in a pharmacology course, especially on the practical side, to give the student an insight into clinical research, so that he is interested in advances and competent to assess the value of work he may read about A student should be encouraged to keep in touch with current literature, by guidance in medical reading during his clinical training he will soon develop good habits in this respect The fundamental principle is to interest the student in his subject, and if this is done he will have the impulse to keep abreast of advances in it

OUR PLACE AMONG THE ANIMALS

In teaching zoology my own aim has been to bear in mind these issues the student needs a comprehensive picture of the vertebrate body as an integral whole as

REGISTRATION

No-one is a *legally qualified* medical practitioner unless his name appears on the Medical Register kept by the General Council of Medical Education and Registration of the United Kingdom The Council is a standardising body, ensuring that there is a definite minimum of medical education and examination requirements and it is responsible for discipline within the profession Any application to be admitted to a school of medicine on beginning the medical curriculum proper should be addressed to the dean or other appropriate authority of the school to which the applicant desires to be admitted

The number of students admitted to British medical schools during 1940–41 was 2415 The entry for 1941–42 is estimated at about the same figure, as shown in the graph, though the returns are not yet quite complete The quota imposed on admissions to medical schools is likely to maintain numbers at about the same level while the war lasts a basis for subsequent more detailed study of human anatomy and physiology, he needs a grounding in the cellular structure of the body as a basis of later studies in histology and pathology, and some familiarity with animal phyla as a basis for the study of tropical medicine and helminthology; if he intends to take up public-health work he should have a thorough grasp of principles of heredity. I therefore divide my course into three parts.

I. *How animals work.*—The physiological anatomy of the vertebrate, with special reference to the frog and man, but with such references to other vertebrates or non-vertebrates as illustrate particular functions (e.g., ciliary action), practical work, including dissection of frog, rat, dogfish and pigeon, demonstrations on selected topics including reflex action and the reversible oxidation of respiratory pigments (hæmoglobin and hæmocyanin).

II. *How animals develop.*—Development, histology and heredity, the nature of sexual reproduction and its manifestations in relation to habitat, different types of embryonic development from the same standpoint, characteristic animal tissues, chromosomes, sex differentiations, genetics, including the chromosome map, experimental modifications of development. Practical work on development and fertilisation of the sea urchin's egg alive, demonstrations of organogeny, microscopic study of living tissues as well as micro preparations, demonstrations of genetic exponents (drosophila), quantitative genetic problems for solution.

III. *How animals differ.*—Survey of the animal kingdom with special emphasis on parasitic groups, insect (and other) vectors of disease; methods of control based on understanding of life cycles. Since time is too short to study all animal parasites in detail, I aim at giving as comprehensive as possible a picture of the rôle of animals vis à vis human health.

TOO LONG IN LEADING STRINGS?

I should hate to see the present six-year period increased in any way before qualification. As a past student and present parent of two medical offsprings I think it is long enough but needs reform.

Preclinical.—Is it necessary to include botany? My zoological colleague has set out above his ideas on his subject which appear to me to be excellent and calculated to give good biological foundations.

Anatomy.—In many schools this remains divorced from the doctor's life-work, for though it must always be a basic subject much detailed memorising of facts is quite unnecessary; to learn many minute muscular attachments (such as those of spinal muscles) and to acquire the ability to identify the right from the left trapezium, is frankly a waste of time and effort, since such details are forgotten as soon as the examinations are over. An old teacher of mine used to say that a surgeon should know his anatomy as a taximan knows London—able to get from A to B by the best route, avoiding traffic blocks and congested areas, but not necessarily knowing every street and shop en route. There is much in this. There should be more study, say, of the shoulder-joint as a functional unit, and not so much of every detailed attachment and bony irregularity. The textbooks, examiners and teachers will have to collaborate if this is to come about. I would like to see anatomy studied in 4 terms (not 5 as at present), but continued on a practical and clinical basis into the next period. We should thus save three months.

Physiology.—I should like to see this kept to 4 terms on similar lines to anatomy, and the physicians and physiologists must fight it out. It seems to me that physiologists, like anatomists, are tending to get further and further away from realities as affecting the student of medicine. They are becoming too "pure."

Surgery.—The high degree of specialisation which is immediately upon us has its particular dangers for the teaching of basic surgery to students. Teaching hospitals are becoming a conglomeration of specialists and the education of future professors of surgery will in itself be a problem. However, the problem of the dresser is the urgent one, and there is a danger of lopsidedness if, say, he has three months of urology followed by three months of proctological practice. I think every dresser must start with three months of basic teaching with the professorial unit which must be kept on the ground floor of the surgery, working in wards where ordinary day to day surgery should form the basis of his early training. After this he can have another three months with one of the higher flights. During the first three months some collaboration might be made with the anatomist to give a clinical basis to his anatomy.

A writer in your journal some months ago commented on the immaturity of the medical student; this is because we keep him so, and ripen him on one day when he suddenly qualifies. We do not use him sufficiently as part of the machinery of hospital practice or give him responsibility, though I am sure he is worthy of it and would respond to it. His contact with his obstetric cases more or less on his own gives him a genuine feeling of at last being of some use, and it is good for him. I want him to have at least three months in his fifth or sixth year as a clinical assistant in residence, with some duties and responsibilities. If it can be fitted in as a part of the same plan to "ripen" the man more gradually I should like each student to be appointed to approved practitioners for duty in the health centres which are pretty certain to be a part of our new practitioner organisation. After qualification every student should have a minimum of six months residence at approved hospitals and be paid for this service.

SEEING ANATOMY WHOLE

Is it not time that botany was eliminated from the medical course except for some lectures on general aspects of importance to the medical student from the point of view of a biological background, and such points as are necessary for the later understanding of photosynthesis, bacteria, &c.? I cannot see that there is need for an examination if a man is signed up for a short course of such lectures, possibly with practical demonstrations. We no longer collect simples, organic chemistry provides many of our drugs, and the chemist in any case makes up our prescriptions. The opposition will come from the botanists, whose existence is in large measure dependent on medical botany courses.

I should like to see students' anatomy dissection preceded by a rapid specimen demonstration, by an expert, of the dissection of the whole body. Then the student would remember the body as a whole, would not be relatively ignorant of the junctional regions (thorax to arm, and to head and neck, abdomen to leg) as at present. He would also be able, after such a demonstration, to dissect much more rapidly himself. With regard to the study of structure and function, why not introduce many more cinematograph and X-ray films, properly analysed, into the teaching? For function in many cases is movement, and that is best demonstrated by showing the structures in movement.

BEST OF ALL POSSIBLE WORLDS

The curriculum as it stands is a good one and many good doctors have been produced by it in the past. As for the preventive aspects of medicine, I seem to spend most of my life in teaching and emphasising them in relation to obstetrics and gynæcology, and I cannot see that this emphasis can be much improved except in the obstetric functional disorders and diseases that dovetail with general medicine, surgery and pædiatrics. As regards opportunities for the study of social medicine and general practice, speaking as one who was in general practice for a number of years, my feeling is that the man who has been well trained in general medical and surgical principles in the outpatient and inpatient practice of a general hospital is fitted to carry on general practice and should have no difficulty in adjusting himself to conditions that are different chiefly in that he has to assume greater personal responsibility and make decisions on his own account. By the Scottish system the student is attached for a period to a dispensary doctor, whose practice he attends and whose district he visits just as he would if he were an assistant in general practice. A short course in psychology is, of course, very desirable but I think that is now admitted by everyone. As an examiner of long experience I would say that it must be rare indeed that bad or unsuitable questions are set and I cannot give any examples of bad questions being set in recent years. If some system could be devised whereby the students' teacher could always take part in his examination, especially in the clinicals, it would be all to the good.

—OR THE WORST ?

I feel like the captain of a liner which has received a big smash and who is remaining continuously on the bridge, anxious to keep his ship afloat and bring her safely into port, when he is importuned to help prepare a programme for a concert and discuss the decoration of the saloon for the next luxury cruise ! I have something to do with details of a syllabus in my official capacity and I can never get the authorities to agree on the details of any subject Recently we had the anatomists to meet us to hear their views about the syllabus , and a fine mess *they* would have made of it This I fear applies to practically everything You must have a syllabus I suppose, but however detailed its conception and description it is open to criticism So what use would it be for me to say what animals should be dissected in the zoology course, what experiments conducted in physics ? The teachers and examiners in these subjects would never agree Examinations ? Everybody agrees they are not satisfactory and everybody agrees that there is no satisfactory substitute And there is no chance of agreement between examiners themselves The questions I should condemn are the very ones which a colleague at least equally experienced might particularly approbate And conversely

A GOOD UNDERSTANDING

If, as you suggest, the aim is to produce wise doctors, we must, I feel, go farther back than the medical curriculum , for wisdom I take it implies not only the possession of experience and knowledge, but the power to apply them skilfully and critically—and for that the first essential is ability If we could devise some method of selecting as students of medicine only those of high intellectual ability we need not worry too much about the details of the curriculum itself During the past decade the number of applicants to enter each medical school has probably been greater than the number of places available, but there has been little, if any, critical examination of the basis of selection All sorts of factors affect the decision local considerations, blood relationships of the candidate, the school record, confidential reports by schoolmasters and others, the interview in an attempt to assess that indefinable abstraction character, not to speak of the gentle art of ear-biting I confess I find it difficult to believe that any of these considerations is of real help in our search for wise doctors, except possibly the school record And individual variation among the schools in the country makes even the school-record of doubtful import

I would prefer that entrance to a medical school be based on a competitive examination on 4 subjects (English language and literature, including history, and any other 3 professed by the candidate) If it be argued that such a policy would mean putting too much weight on examinations, and would be hard on the slow developer, I can only say that it would be better than the haphazard methods of selection employed at present, and would at least have the merit of being based on a test, the results of which can be measured with a fair degree of accuracy Besides I am not impressed by the attacks constantly made on examinations, often by middle-aged mediocrities and sometimes based on a psychological reaction of the " inferiority " type After all, what is life itself but a test or, if you will, an examination Granted a corps of students of more than average ability, the only other desideratum is a body of teachers with the right attitude towards medicine No-one is likely to doubt the ability or the technical efficiency of the teachers of the present day what might be questioned is their outlook on their subjects in relationship to medicine And yet the recipe, stated in general terms, is simple If each teacher were to recognise that his own special subject is only a focus of interest in the great domain of general biology , that structure is of importance only in so far as it relates to function , and that the only things that really matter in medicine are the preservation of normal function, the study of the means—chemical, physicochemical, environmental, and genetical—by which function is disturbed, and the methods by which it may be restored or alleviated, then all the questions of medical education, so commonly canvassed, would become details of minor importance

There is perhaps one thing more—a careful study of the thirteenth chapter of Paul's first letter to the Corinthians, in itself a not inconsiderable contribution to the study of general biology If it were thoroughly digested by every medical student it would help make the doctor not only wise and comprehending, but human, gracious, and kindly

WHO SHOULD TEACH PREVENTIVE MEDICINE ?

We are all being encouraged to develop the preventive outlook in teaching and to devote more time to instruction in this important subject One of the principal difficulties is that the teaching of preventive medicine is largely in the hands of local medical officers of health and they have proved incompetent as teachers It seems that the practice of preventive medicine does not produce a body of inspiring teachers and, until the schools can have on their staff teachers with a real enthusiasm for their subject and a capacity to impart its principles to others, we shall make little headway I think that one possible line of approach would be for the universities to appoint more whole-time professors in this subject These professors would be able to collaborate with the clinical teachers who, in their turn, would be stimulated to emphasise the preventive aspects of clinical practice At present the clinical teachers never see the public health teacher, who is not a member of the hospital staff and who does not, therefore, have much opportunity of making contacts with his fellow teachers The whole question is bound up with the examination problem When the examiners devote more space to the preventive aspects of medicine the teachers will perforce follow them

I would say that the bad examination question is the one that asks for facts (e g , " describe the signs, symptoms and treatment of typhoid fever ") while the good question tries to find out whether the candidate can use these facts (e g , " discuss the investigation of a patient in the second week of a febrile illness in whom the only physical sign is an enlarged spleen ") The first question is pure book knowledge, the second is one which requires some mobilisation of that knowledge The trouble is that the first type of question is much easier to set and to correct A thorough revision of examinations on these lines might require a larger number of examiners

TRAINING IN SCIENTIFIC METHOD

In universities other than London the teachers have a considerable say in arranging that the questions set in examinations should include some of those parts of the course which have received a special emphasis in teaching owing to the special tastes and experience of the teachers at that university This ensures progressive development of the curriculum by allowing teachers some freedom and initiative in developing the subjects taught In the London schools, by contrast, the development of the curriculum on new lines is severely hampered by the system of what amounts to an external examination

With regard to anatomy and physiology, we are falling between two stools We are attempting in five terms to teach students all the factual material which is likely to be of value to them in later years, and at the same time claiming to give them an education in medical sciences Science, however, requires a training in the appreciation of evidence which can only be obtained from detailed knowledge in a few small fields, and this is incompatible with the examination requirement that students should have a thorough knowledge of the whole subject We ought to lighten the load of factual knowledge by transferring information which is included for strictly vocational purposes, and not as part of the training in scientific principles, to the clinical years and teaching it in courses in applied physiology, comparable with those on surgical anatomy This would lighten the load in the preclinical years and enable students during that period to receive an education on scientific lines Judging from what the teachers at hospitals say it is such scientific training that they value most highly in the students coming into the wards, and it should be possible to combine this with a factual basis sufficiently extensive for practical purposes without being detailed to the point of frustrating interest, as at present

EXAMINING FOR ABILITY

The question whether the examinations are faulty or not depends on the view held as to their purpose. If the final examination aims simply at assessing the state at that time of the student's technical competence then the present examinations serve this purpose. If, however, the aim is to test the student's understanding of his subject and his capacity to learn from experience, then the present examinations fail. If they are to be elevated from simple tests of technical competence to tests of education then they must lay much less stress on factual knowledge and far more on ability to use facts. The type of question, for instance, must change from the favourite kind such as "describe the symptoms and signs of bronchiectasis" to one such as "write an essay on one of the following four subjects. The significance of (1) hypochromic anæmia, (2) œdema, (3) vertigo, (4) pain after food." And more use should be made of the case commentary. It is possible that such a reform of examinations would require that the final examination be split into two parts, the first to aim at eliciting the student's grasp of his subject, the second to assess his technical knowledge and thus his competence to practise.

THOROUGHNESS

To teach chemistry in preparation for pharmacy and the proper appreciation of metabolism emphasis should be laid on analytical reactions, the law of mass action and its application to hydrogen-ion concentration and pH, and the quantitative aspect of chemical reactions. The reactions of organic "types" and "groups," rather than the preparation and properties of specific compounds, should be taught in preparation for a detailed study of proteins, fats, carbohydrates, purines and those classes of compound of especial importance in medicine. Enzymes and the nature of enzyme action should be briefly taught.

The student should supplement his study of elementary physics by obtaining a practical knowledge of the common applications of electricity, including a thorough understanding of the safety devices which are designed to protect electrical appliances from damage and their users from risk of shock. Such a foundation will enable him to follow with appreciation the experiments which led to the discovery of X rays, and to profit from a preliminary exposition of the principles of the radiological equipment encountered later in hospital.

Our teacher in biology suggests that the types suitable for illustration of most of the biology principles would be the mosquito, earthworm, skate, frog and rabbit. Classes of applied anatomy and physiology, the study of the living subject and of X-ray appearances, and observation of the abnormalities produced by disease appear to be essential if the student is to correlate human structure and function.

To induce Edinburgh students to keep abreast of advances in therapy the Royal Medical Society, by weekly discussion and the provision of library and medical magazine facilities, does much in this direction. In Edinburgh there is a system of dispensary practice whereby senior medical students are out on their own in the various districts attending the sick poor, and call in the physician in charge of the dispensary in cases of difficulty. This is an extremely valuable thing and might well be copied in other medical schools. The lecturer in public health, a former medical officer of health of Edinburgh, is able to show to his students the practical working of the public health services in the city.

Improvement of examinations is a difficult matter. Some students are cool and collected in examinations while others are flustered and mentally paralysed, but a recognition by the examiner of the abnormal mental condition of the student can be made a factor in alleviating or modifying a student's perturbation.

RESILIENCE

I want the whole of the medical student's course *directed* from the start, and I think this might be done without departing from its cultural breadth. The process begins when schoolmasters are advising parents and children on careers, having regard to their intelligence and aptitudes. At least two of the sciences should come into matric.

In both zoology and botany much attention should be paid to the structure, function and differentiation of cells. Experiments in physics should have relation to radiography, to the passage of fluids in tubes (blood-vascular system) and to conductivity, drawing a comparison between a wire and a nerve. Organic chemistry should be taught in more detail, while some inorganic chemistry, not related to medical students' work, should be omitted. Chemistry should lead on to interest in synthesis even of vitamins and sulphonamides. Pharmacy and metabolism are best associated by linking teaching in these subjects with the teaching of organic chemistry.

Anatomy and physiology should be approached from the outside through study of the human model by the use of X rays, and the student should become acquainted with the normal heart and lungs and should learn the use of the various scopes. Physiology can teach the normal behaviour of muscles, vessels and nerves. So much that might come under anatomy and physiology has to be taught with the clinical subjects. Normal biochemistry and biophysics are part of physiology. Structure and function should not be divorced under two professors. I would welcome a professor of human biology. What a meaningless maze the nervous system is when instruction on structure and function are dissociated. It should be *human* anatomy and *human* physiology, and these subjects should be taught by medical men who have had experience of what is required from a doctor. The teaching should be as applied as possible. Clinical teachers should be associated with the teaching and there should be an overlap of the early clinical studies with anatomy and physiology. I do not think any teaching should be in the air, and do not like the students to say "What is the good of this to me?" and "I wish I could get it over." All medical students should be interested in what they are learning from the start, and should be stimulated to a constant curiosity and state of inquiry. I would like the whole course to be carried out by one corporate body of teachers discussing together, and interested in, the training of the medical student. I am against teaching the preliminary sciences in schools and in institutions dissociated from hospital and clinical work, one thing must be always leading to another. For example morbid histology should not be separated from the teaching of normal histology, and human tissues should be used for the latter. There is much to be said for the anatomy teacher being a surgeon and the physiology teacher a physician, again the old-fashioned idea. I do not like a professor of physiology asserting that his is a great scientific subject which others might learn without passing on to clinical medicine; as a matter of fact this hardly ever occurs. Advances in therapy with us appear in the pharmacology course, and our professor of pharmacology is associated with clinical studies.

In regard to the clinical course, it is impossible to cover everything and there must be some selection; early diagnosis is important, also children's diseases and child care. Train the students to be good general practitioners. Training as specialists must be postgraduate. In common I imagine, with other schools we are not able, with the already overcrowded curriculum, to place students for training in general practice. They see something of the problems of general practice in large outpatient departments. In my own large one they hear the letters dictated to doctors.

All our clinical teachers have been incited to introduce preventive medicine into their curriculum. I always try to teach prevention by going into causation. For example I will talk about the causation of appendicitis and of peptic ulcer. Social medicine must extend, and the professor of preventive medicine will become professor of social medicine. Social medicine relates both to the individual and to his environment. Apart from what is done already, I would stress the care of children of preschool age, in nursery schools and elsewhere. Much illness might be prevented which occurs in school life later. Look after the teeth and throat; attend to diet to avoid rickets. There is much to be said for annual physical assessment of the individual even from early in life. We have started it with our medical students, including X-ray examination. The doctor must have a far greater hand than at present in housing, feeding, clothing, town and country planning, recreation, industrial medical problems, and much else

As long as the main demand of the public is for curative medicine the student must be trained to supply it A different education of the student means a different education of the public, and public education in social medicine must be carried out by doctors They must learn to teach the public and must intrude into such educational fields as the Workers' Educational Association, university extension lectures, and instruction arranged by local authorities The medical student, and particularly the postgraduate student, must be taught how to teach the public In these and other ways we may in time get a different public demand

UNITY IN TRINITY

In this school there is close cooperation between the professors of physiology and biochemistry on the one hand and the professor of anatomy on the other and therefore the divorce referred to as existing elsewhere is here replaced by a happy union We also have close cooperation between the professor of chemistry and our professor of biochemistry, himself a distinguished chemist If I had my way in the medical curriculum I would reduce the number of lectures, certainly the number of compulsory lectures, in this age of abundant books, but would insist on regular attendance at all practical courses To light in newly qualified men the impulse to keep abreast of advances in therapy, I can think of nothing better than that you should present each one with a free copy of the *Lancet* weekly After a year or more each practitioner would doubtless become a subscriber

---

Medical Schools

The earthquake which tossed our medical schools here and there in 1939-40 has had the usual fate of earthquakes it has lost its news value and become merely an episode which man and nature between them have turned to good account Most of the medical schools are now running sweetly, as the engineers say, in the surroundings to which war has brought them, and there is little to add to the story which we told last year The customary survey may thus be curtailed in favour of other matter more immediately interesting

At Oxford University there has been no important change After completing their premedical and preclinical courses students can still take their full clinical course at the Radcliffe Infirmary There are now 170 students doing different parts of their clinical work, and the quota allows the yearly admission of 71 new students to the medical school—64 men and 7 women Any vacancies left by the men may be taken by women Details of the preclinical course may be had from the Acting-Dean of the Medical School, University Museum, Oxford, and of the clinical courses from the Clinical Sub-Dean, at the Radcliffe Infirmary The diploma in ophthalmology is being granted as usual and information about the course for it can be obtained from the Reader in Ophthalmology, at the Oxford Eye Hospital in Walton Street There is no dental school in the university

Cambridge University, too, has seen no cause to change its war-time pattern for medical students, except that the first examination—in chemistry, physics, botany and zoology, and organic chemistry—is being held in full four times a year, which gives the premedical student little excuse for dawdling over any part of it Students take finals after spending two years and nine months in one of the teaching hospitals outside Cambridge —though senior students can receive some instruction at Addenbrooke's Hospital before they qualify if they wish The last examination for the diploma in medical radiology and electrology is to be held in October, after which the diploma will no longer be given Cambridge provided 5 Rockefeller students, 2 of whom have sent us their impressions Particulars of admission to the medical school may be obtained from the Registrary, University Registry, Cambridge There is no dental school in the university.

London University offers preclinical courses at King's College, University College and Queen Mary College Students usually complete their clinical work at one of the London teaching hospitals In order to help students to qualify quickly an additional second examination (anatomy and physiology, organic chemistry, biochemistry and pharmacology) is being held in November this year, and the final examination is now held in October and April (instead of November and May) The final surgery examination is now to consist of a three hour paper, a clinical examination, and orals in surgical pathology and surgical anatomy and appliances Examination fees paid by students who are prevented from sitting by national service are to be returned in full The examination for the diploma in clinical pathology which should have been held in October, 1942, has been postponed until January, 1943 The university also offers diplomas in bacteriology, dietetics, medical radiology, public health, and psychological medicine The courses in bacteriology and public health are suspended during the war There have been 3594 students in the medical faculty during the year Present regulations for medical examinations may be obtained from the Principal, at Richmond College, Surrey Dental students attend the Royal Dental Hospital of the London School of Dental Surgery at 32, Leicester Square, London, W C 2 Students are prepared for the BDS degree, and the university also offers a licensing diploma Particulars of the course may be had from the Dean

King's College is the largest preclinical school in London, and has to limit the number of entries admitted each year to 120 It takes most of the preclinical students of Charing Cross, King's College Hospital, St George's and Westminster Since the beginning of the war, the medical faculty has spent one year in the University of Glasgow and two at the new medical school of the University of Birmingham In both universities it has been possible to carry out the work of the medical departments successfully and as independently as in London It has now been decided however that the faculty should return to London, and next session begins at King's College, Strand, on Sept 22 when the present generation of first and second year students will come as strangers into their own spacious laboratories, lecture theatres and dissecting rooms Queen Mary College, which is housed at King's College, Cambridge, takes preclinical students from the London Hospital and elsewhere, during the year there were 30 taking anatomy and physiology, and 14 the premedical courses University College provides the preclinical courses for most of the students of University College Hospital Those taking premedical courses in biology, physics and chemistry are working at Bangor; the second year students, doing anatomy and physiology, are at Leatherhead The close contact between staff and students who live in the same buildings has been a great success, and the advantages are perhaps reflected in the fact that three University College men were chosen to hold Rockefeller studentships (one of whom has contributed to our collection of letters from those argonauts)

The London Schools

St Bartholomew's Hospital reports no great changes The preclinical students are still welcomed at Cambridge and are completing full courses there In London and the sector hospitals clinical teaching has gone on as usual

The clinical students of Charing Cross Hospital are still at Chauldon House, Boxmoor, there are quarters for 60 of them there, and they share dining, recreation and common rooms, as well as silence and reading rooms and a pathology laboratory Owing to war-time demands on staff the medical and surgical firms have been reduced from six to four, and the beds available to each firm have increased proportionately, students work as clerks and dressers at Ashridge hospital where, with 1200 beds at their disposal, they have first-class clinical experience For clerkships in special departments they attend the parent hospital, Ashridge and Stanmore Hospitals, Redhill County Hospital and others Midwifery experience is gained at Edgware In their final year they are posted by rota to live in at Charing Cross or Ashridge as emergency dressers, and during this time they become perfect in the technique of blood transfusion.

increased emphasis on social, preventive and industrial medicine without a corresponding whittling down of the time allotted to other branches of study is congesting the already crowded curriculum, especially since the clinical period was shortened Resident appointments are plentiful since some of the sector hospitals must be supplied, as well as Charing Cross

ST GEORGE'S has more to report than most of its fellow teaching hospitals There has been a return to London Routine practical classes in pathology, bacteriology and biochemistry were already being held at the parent hospital at the beginning of the year, but second year clinical students continued to work at the West Middlesex Hospital up to May 1 after which they returned to St George's for all courses except midwifery; these continue to be given, by courtesy of the Middlesex County Council, at the West Middlesex Patients have been increasing at Hyde Park Corner during the year and the students have thus had plenty of experience; but lest there should be a return of heavy raids to empty London again, the hospital has provided its convalescent home at Wimbledon with modern equipment, and 120 beds will be available there for teaching if they are needed. The medical school has rented a country house near by which is already fitted to serve as an emergency medical school with laboratories If all is quiet the Wimbledon establishment will be used merely as an annexe In either case the students will be provided with good libraries, museum and canteen, and plenty of clinical experience. The Wimbledon site has the advantage of twenty-three acres of wooded parkland on a southern slope, in easy reach of transport to town

At GUY'S HOSPITAL everything has been going well The preclinical students are still working at Tunbridge Wells, and their examination results have testified to the benefits of a country life The classrooms and laboratories are within easy cycling distance of each other, so that no transport problems arise, and students enjoy something like the atmosphere of a university town The clinical students still have the run of the sector hospitals and of Guy's itself The shortage of staff has thrown much work on those who remain, teachers of the preclinical students have been particularly hard pressed because, owing to the small size of classrooms in Tunbridge Wells the courses there have to be duplicated, but they have worked strenuously and keenly to maintain teaching standards Applications here, as elsewhere, are extremely numerous, but the quota maintains admissions at the prewar level

KING'S COLLEGE HOSPITAL has little fresh to report Clinical students still work at Horton Hospital, Leatherhead Emergency Hospital and finally at King's itself. Midwifery experience begins in the hospital lying-in-ward and the neighbouring district, is continued at a borough hospital and completed at a new county hospital This plan is so successful that the medical school authorities hope the principle of access to beds outside London will be perpetuated The diabetic department of the hospital, opened in 1940, is available for teaching and research There is an active dental school

The LONDON HOSPITAL remains the headquarters, but premedical subjects are taught at Queen Mary College now at Cambridge (see above) and the departments of physiology and anatomy are also guests of that university Students attend the annexe at Brentwood as well as the parent hospital for their clinical experience, their pathology course is given by their own teachers at Chase Farm Hospital, Enfield In their second clinical year they may be appointed as student house-officers, at a salary of £50 a year, to the sector hospitals During their final year all students return to the London for ward work and systematic lectures The hospital has its own dental school

The number of students at ST MARY'S HOSPITAL remains stationary, though the excess of applicants over vacancies is larger than before St. Mary's is fortunate in that both school and hospital buildings remain undamaged; but it has been the policy of the school to disperse students to some extent Thus the first year continue to be the guests of Berkhamsted school, while students in their clinical years are still working in the large EMS and Middlesex County Council hospital at Harefield and in three other sector hospitals in addition to St Mary's itself The whole of the second MB course and the latter part of the clinical teaching are carried on at the parent hospital Thus students have the chance to see a large variety of clinical material in the sector, and also to participate in organised student life at St Mary's The Home Guard and athletic clubs have always flourished during the war years, and in the past year the medical society has had an average attendance of over 130 at its meetings and active musical and dramatic societies have also grown up. The large number of resident posts available in the sector continue to provide house appointments for all students on qualification

Preclinical students of the MIDDLESEX HOSPITAL have been working at the University of Leeds, thanks to the kindness of the vice-chancellor, but they are expecting to return to London this autumn The clinical students continue to work at the sector hospitals at Aylesbury, Northwood and Willesden as well as at the Royal Hospital, Wolverhampton, and the Middlesex itself All is going well

The preclinical students of the ROYAL FREE HOSPITAL (London School of Medicine for Women) are still working at the University College of the South West, in Exeter, and will not be returning to London for the present The work at Arlesey has increased and students are getting much more clinical experience than was possible for them a year ago Some midwifery beds have been opened at the Royal Free itself, and students are also getting plenty of cases at Shardeloes, Amersham, at the Mother's Hospital, Clapton, and in Exeter Otherwise there have been no changes since last year

ST THOMAS'S, which perhaps suffered worst of the London teaching hospitals in the raids, has shown her qualities as a phœnix The premedical and preclinical students are at Godalming, where laboratories and classrooms have been set up with the coöperation of Charterhouse School At Hydestile, Godalming, a new St Thomas's has been opened under the direct administration of the governors of the parent hospital, and this is now the chief centre of clinical teaching, which is maintained without a break in traditional high standards. The pathology department has been established in a house in Godalming leased and modified to receive it Since July the final-year students have left the sector hospital at Guildford and returned to St Thomas's in London, where beds are increasing again and outpatient teaching is almost back to normal

At UNIVERSITY COLLEGE HOSPITAL experience has confirmed the wisdom of concentrating the students in few centres At the beginning of the war they were distributed in small groups in the various hospitals of sector IV. This was not satisfactory, and every successive step in concentration has brought an improvement in education By grouping students together it is possible to make better use of trained teachers, to coordinate clinical teaching with teaching in other subjects, such as clinical pathology, and to concentrate libraries, museums and laboratories, and it has also been found to foster community learning among the students themselves An experiment in teaching is being made at Leavesden It seems that students approach their cases prejudiced by the category in which they find them placed thus they may imagine there are "surgical" peptic ulcers and "medical" peptic ulcers, which need different treatment To overcome this artificial approach the medical and surgical units are combining as one firm, and students appointed to it clerk for all types of patient and are taught by both the medical and surgical chiefs Clinical experience is gained at Leavesden, at Stanboroughs Hydro, Watford, and at University College Hospital itself There is a dental school

The WEST LONDON HOSPITAL school gives preference to women students reading for the London University medical degrees but other students are accepted when vacancies are available During the first two years of the war the number of entries fell but they have now increased and at present the school cannot accept all the students who apply The standard of the students is very high, only about 10% of applicants being ultimately selected As the hospital has suffered no damage from enemy action it has not been necessary to make use of the sector hospitals, and teaching is still to be carried out at the West London, with the exception of practical obstetrics which is taught at one of the maternity units of the Middlesex County Council House appointments are available for students on qualification but the reduction in resident staff required by the authorities has meant that fewer of these posts will be available during the coming year In spite of further depletion of the honorary staff to satisfy the increasing needs of the Services, the teaching in all departments is satisfactory during the past year

Westminster has carried on with absolutely no alteration in the position established twelve months ago The hospital is full to capacity and many applicants have to be refused Arrangements for clinical teaching at Staines and Ripley and at Westminster itself have been maintained though the loss of teachers to the Services has meant a heavy strain on those who are left The examination results, however, have shown it to be worth it

The School of Dentistry of the Royal Dental Hospital of London admits students who have passed their premedical examination in zoology, botany, physics and chemistry They take courses in dental mechanics, metallurgy and special anatomy for the first two years, and during this time they also normally study general anatomy and physiology at King's College , at present, since King's is out of London, the anatomy and physiology courses are being held at the Royal Free Hospital, but with the return of King's to town this autumn presumably the old plan will be resumed For general medicine and surgery the students attend clinics at Charing Cross Hospital There are also dental schools at Guy's, University College Hospital, King's College Hospital and the London, but the other London teaching schools offer no organised teaching for dental students , medical students of those schools, however, who wished to study dentistry could of course be credited with the general courses they had taken there

Other English Schools

The University of Durham has not been called upon to meet any new problems in medical education during the past year The medical school of the university is at King's College, Newcastle-on-Tyne, and fortunately work has continued there without interruption There have been no changes in the regulations governing medical degrees The university offers a diploma in public health but no course will be held during the coming academic year unless a minimum of 6 candidates enter No course has been held for the diploma in psychological medicine for some time, and the university offers no other diplomas There is a school of dental surgery preparing students for the usual degrees , some alterations have been made, during the year, in the course for the degree of bachelor in dental surgery, making it more comprehensive and in line with modern teaching Particulars of medical and dental courses may be had from the Dean of Medicine, The Medical School, King's College, Newcastle-on-Tyne

The Birmingham University * medical school has also escaped any serious disturbance Clinical teaching goes on at the two branches of the Birmingham United Hospital—the General and the Queen Elizabeth Hospitals The Queen's Hospital, which had been an integral part of the medical school for a hundred years, has now become the Birmingham Accident Hospital in charge of a director and a whole-time staff , it accepts only fractures and other injuries, and, being still an associated hospital of the medical school, offers teaching to students A reader in pharmacology has been added to the staff of the school during the year As a war-time measure associated with the EMS, a thoracic surgical unit has been formed at the Queen Elizabeth Hospital, and this, it is hoped, will become permanent Short courses of lectures on medical problems in industry have been arranged for industrial medical officers and nurses, and in addition the university grants a certificate to state registered nurses who have attended a course of instruction in the subject in conjunction with their work at the Accident Hospital The work of the dental school is unaffected, and there have been no changes in regulations governing medical and dental examinations since last year Neither the examination nor the course for the diploma in public health will be held during the war, and the university grants no other medical diplomas Particulars of all medical and dental courses are to be had from the Dean of the Medical Faculty, the Medical School, Hospitals Centre, Birmingham 15.

Liverpool University * has carried on with no change since last year A vacation term is now held during the long vacation for students about to begin their final year , this enables them to complete their statutory classes so that during their final year they can take resident posts in hospitals The school of dentistry is working as usual, and there have been no changes in the regulations governing medical or dental examinations The courses and examinations for the diplomas in medical radiology and electrology, and in public health are at present suspended The courses for the diplomas in tropical medicine and tropical hygiene will be held if possible and an announcement about them will be made later Information about medical and dental courses may be sought from the Dean of the Faculty of Medicine, University of Liverpool

At Manchester University * there are few important developments to chronicle Students who have completed all their appointments are allowed to sit for the final six months earlier than was formerly possible, but the university teachers are resolved that there shall be no lowering in the pass standard Students have the option of living in the medical hostel, Lister House, which adjoins the Royal Infirmary and life there seems to be busy and happy The heads of departments have formed a curriculum committee which has had several meetings and laid plans for postwar developments Medical inspection of all medical students is to begin as soon as possible, and staff-student meetings continue to be useful Clinical teaching has been modified to allow students to begin work as clerks and dressers as soon as they come into the wards, and to combine their post mortem clerkship with other appointments Final students can now attend other hospitals besides the infirmary, and several new clinical teachers have accordingly been appointed to the university staff Final year students take resident posts as student-locums In July, 33 candidates received the double degree (1 with first-class and 3 with second-class honours), and there were more distinctions than usual in anatomy and physiology , for the second year running a Manchester student won the Hallett prize on the primary fellowship examination With a quota of 67 men and 22 women the medical faculty has to refuse many applicants

At Sheffield University * there have been no material changes, though many ideas for changes are in the air The applicants to the medical school, both men and women, far exceed the number of places available under the Ministry of Health quota There are no university medical diplomas The dental school is continuing work as usual Those seeking further information should apply to the Dean of the Faculty of Medicine, the University, Sheffield 10

At Bristol University there has been little disturbance to serious study from air-raids this year, and work in the medical school has gone on as usual The department of anatomy, which suffered in 1940, has been partly reconstructed and furnished with a new dissecting room Competition for entry has become keener since admissions were limited by quota A new prize in pathology has been founded by Professor and Mrs T F Hewer Amended regulations for the second part of the medical curriculum will come into force next session , these ease things, from the student's point of view, by allowing him to take the second MB examination in two sections—anatomy and physiology in March and pathology and pharmacology in June Formerly he had to take all four subjects together in June The course and examination for the diploma in public health is still in abeyance, and the university offers no other medical diplomas No changes are reported in the dental school Details of the medical and dental courses may be obtained

---

* The entrance requirements for the Universities of Manchester Liverpool, Leeds, Sheffield and Birmingham have been modified since the beginning of war , they may be obtained from the Secretary, Joint Matriculation Board, 315, Oxford Road, Manchester The faculty entrance requirements differ in each case from those of the university , they can be obtained from the Dean of the Faculty of Medicine in each university

from the Dean of the Faculty of Medicine, University of Bristol.

At LEEDS UNIVERSITY* the most serious of the many problems of the year has been to reduce the clinical period of teaching from 36 to 30 months without lowering the standard. The first group of students able to take the shortened course are those due, under the old system, to qualify in March, 1944; they will now be able to complete their course by September, 1933. There has been further loss of teachers to the Forces but retired members of the staff have come back to take their places. The university is sorry to lose the preclinical students of the Middlesex Hospital, who return to London with their teachers this autumn. The association between the two medical schools during the past two years has been happy. Work at Leeds has gone on undisturbed, and the numbers seeking admission to the medical school have been greater than ever—far greater than the Government quota permits or the school could accommodate.

Other Schools in the United Kingdom

The WELSH NATIONAL SCHOOL OF MEDICINE has had no reason to change its arrangements since last year. First-year students may attend any one of the four constituent colleges of the university of Wales, but most of them come to Cardiff. As in other schools, candidates exceed the quota, and in fact for next October there are 160 applications for 44 places. Difficulties in teaching due to loss of staff have been overcome wherever possible by arranging for women to replace men. The new pathology institute in the grounds of Cardiff Infirmary is now virtually complete and its work has been much extended, besides serving the infirmary and many other hospitals it undertakes investigations for private practitioners, and works in close and friendly touch with the EMS laboratories throughout Wales. All work at the institute is associated with teaching; as an example, all local coroner's autopsies are done in the department which is instructive for students. The school has provided senior students as house officers for the infirmary and other hospitals—a plan which is working well. Teaching has been related to war needs, students being specially instructed in the technique of blood transfusion and in field hygiene and sanitation. At the request of the Government and with the approval of the GMC, efforts are being made to shorten the clinical curriculum without lessening its content. There have been no changes so far in the conduct of examinations, however. Courses and examinations for the diploma in public health have been held this year but courses for the diploma in tuberculous diseases have been suspended for the time being. The university awards no other medical diplomas, and there is no dental school. Details of medical degrees and courses may be had from the Provost, Welsh National School of Medicine, Cardiff.

At ABERDEEN UNIVERSITY the curriculum has been accelerated for the present fourth-year students graduating in 1943. The thirteenth term of their course is being held during this summer vacation; it began on July 21 and ends on Sept. 25. The work of the fourteenth, fifteenth and sixteenth terms will be done during the winter, spring and summer terms of 1942–43, and the work of the seventeenth, final, term during the summer vacation of 1943. The courses for the diploma in public health have been discontinued during the war, and the university grants no other diplomas. There is little else to report in the way of change. The new hall of residence was opened last October and is much appreciated and residence is now compulsory for all students in their final year. There is no dental school. Information about medical courses may be had from the Dean of the Faculty of Medicine Aberdeen University.

At EDINBURGH UNIVERSITY there has been a striking educational advance in that the subject of psychiatry is now to be included in the final examination as a separate subject. Edinburgh is the first of the British universities to take this step. The courses and examinations for the diplomas in psychiatry, medical radiology, tropical medicine and hygiene and public health are being held as usual. The university grants no other diplomas, and there is no dental school. So far the war has not seriously affected the medical degree courses, and in spite of depleted staff it has been possible to maintain teaching at prewar levels. Details of medical courses can be obtained from the Dean of the Faculty of Medicine University of Edinburgh.

SURGEONS' HALL the School of Medicine of the Royal Colleges of Edinburgh, holds no professional examinations of its own, but prepares students for the degrees of Edinburgh, London and other universities, or more commonly for the qualifying examinations of the English, Irish or Scottish Conjoint Boards. Systematic classes are held in Surgeon's Hall and the New School, and clinical teaching is provided mainly at the Royal Infirmary. Particulars are to be had from the Dean, Surgeons' Hall, Edinburgh.

At GLASGOW UNIVERSITY it has been possible to continue medical teaching on normal lines. Many of the younger teachers are on active service, and those who remain are adding part-time national service of some kind to their teaching duties. Patients in the hospitals are somewhat fewer, but numbers have been adequate for teaching and it has not been necessary to discontinue any special courses. First second and third year students are required to serve in the Senior Training Corps but matters have been so arranged that any notable interference with study is avoided. They also undertake fire watching in the university. The senior students have been serving as clinical clerks in the EMS during vacations and have also been appointed in increasing numbers as unqualified residents in teaching and other hospitals. At present there are 1070 students in the medical school, of whom about a fifth are women. There are no dental students in the university. The diploma in public health is being offered as usual, and has been transferred from the Faculty of Science to the Faculty of Medicine. The university caters not only for undergraduate instruction but for higher study and research. Details of medical courses are to be had from the Dean of the Faculty of Medicine, University of Glasgow.

ANDERSON COLLEGE and ST MUNGO'S COLLEGE have separate foundations from Glasgow University. Anderson College receives about 700 students a year; courses are given in all preclinical subjects, and clinical training is given at all the hospitals open to university students. The course prepares candidates for the examinations of all the licensing boards and for the university examinations of London Edinburgh, Glasgow and Durham, provided the matriculation requirements of each are met. Particulars of courses may be had from the Dean, Anderson College of Medicine Dunbarton-road, Glasgow. St Mungo's College is the medical school of Glasgow Royal Infirmary, in the grounds of which it stands. It takes 300 students, preclinical courses being given in the college and clinical training in the wards of the infirmary and the special hospitals of the city. Students are prepared for the examinations of the licensing boards and for the examinations of the universities, provided matriculation requirements are met. Further information may be had from the Dean, St Mungo's College Medical School, 86, Castle Street, Glasgow.

There have been few changes at ST ANDREWS UNIVERSITY. Under the quota, 44 men and 21 women can be admitted yearly; applications are much in excess of this, and selection has been difficult. Membership of the Senior Training Corps is now compulsory, but it has been possible to avoid interference with teaching by instituting periods of full-time STC training at the beginning of each term. Courses and examinations for the diploma in public health are suspended for the present and the university offers no other medical diplomas. The work of the dental school has been uninterrupted. Particulars of medical and dental courses may be had from the Dean of the Medical Faculty, University of St Andrews, Dundee.

Despite the fact that Northern Ireland is not included in the conscription, the main difficulty of QUEEN'S UNIVERSITY OF BELFAST has been the absence of many younger members of the staff on war service; nor have the students been behindhand in joining the Forces. The older teachers, including some of those who had retired, have taken on the extra work. The medical school takes more than 600 students and offers a six-year course. The dental school is working as usual. Full information may be had from the Secretary, Queen's University Belfast.

At DUBLIN UNIVERSITY—Trinity College—all goes well There have been no changes in the medical course during the past year, and the courses and examinations for the diplomas in gynæcology and obstetrics, and psychological medicine are being held as usual The courses and examinations for the diploma in public health have been suspended during the war The university grants no other medical diplomas The dental school is unaffected Information about medical and dental courses may be had from the Dean, Trinity College, Dublin The SCHOOLS OF SURGERY, including Carmichael and Ledwich Schools, are attached by charter to the Royal College of Surgeons in Ireland They are carried on within the college buildings at St Stephen's Green, and are supervised by the council of the college Lectures and courses may be attended by medical students who are otherwise unconnected with the college, and women students are admitted Particulars of the courses may be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

In the three colleges of the NATIONAL UNIVERSITY OF IRELAND—University Colleges of Dublin, Cork and Galway—the war has had no serious effect The Dean of University College, Galway, writes that as in other colleges of the university his students are giving help as volunteers in the medical services, but these duties have not interfered with their attendances at lectures or with examination results There are dental schools at Dublin and Cork but not at Galway Regulations governing medical and dental examinations and courses are unchanged and may be obtained from the Registrar, National University of Ireland, 49, Merrion Square, Dublin

Degrees and Diplomas

EXAMINING BOARDS

English, Scottish and Irish Conjoint Boards

The Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of M R C S, L R C P Candidates satisfying the board's regulations in regard to the preliminary examination in general education, are eligible for admission to the premedical examination in chemistry, physics and biology, and are required to complete the professional curriculum subsequently at a recognised medical school As an emergency measure the length of the course has been reduced from 57 to 54 months and candidates are now admissible to the last subject of the final examination after 30 months of clinical study instead of 33 The regulation permitting a candidate to enter for one part of the final after 24 months of clinical study is not affected Some other war-time concessions have been authorised in the regulations for example, clinical study may be undertaken at any hospital provided the dean of the candidate's school is satisfied as to the instruction available and signs the certificate of study Other modifications will be found in the Emergency Regulations which have been published and are to remain in force until the beginning of the academic year following the termination of the war Copies of these regulations, and a calendar showing the dates of examinations, may be obtained, free of charge, from the Secretary to the Examining Board in England, the Examination Hall, Queen Square, London, W C 1

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which, after one series of examinations, held in Edinburgh, or Glasgow, or both, the student may obtain the diplomas—designated by the letters L R C P E, L R C S E, L R F P S G—of all three bodies Candidates may work for the examination of the Scottish Conjoint Board at any of the recognised medical schools of Great Britain and Ireland In 1938 the Triple Qualification committee of management adopted the suggestions of the General Medical Council for an extended medical curriculum, under which the course was to consist of a year of premedical work followed by a five-year medical course, but the committee have reverted to the 1937 regulations as a temporary war measure Under these, the course lasts only five years and includes, in addition to the pre-registration examination, four professional examinations the premedical examination (biology, chemistry and physics), the second examination in anatomy and embryology, physiology, biochemistry and biophysics, the third in pathology and bacteriology, and pharmacology, and the final in medicine, surgery, midwifery, medical jurisprudence and public health Details may be had from the Registrar, 18, Nicolson Street, Edinburgh

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland accept candidates for the L R C P I and L M, L R C S I and L M from most of the recognised medical schools at home and abroad There have been no changes in the regulations since the outbreak of war Full details can be obtained from the Registrar, Royal College of Surgeons in Ireland, Dublin

Apothecaries' Licences

The Society of Apothecaries of London grants the L M S S A Lond to candidates who pass in the primary examination (which is held quarterly) and the final examination Final examinations are held monthly except in September The minimum period of study is normally 5 years, but as a war-time measure candidates will be allowed to sit for the primary examination in anatomy and physiology after 46 weeks' study, provided that this covers a period of not less than 15 months, that is to say, the candidate can sit after four terms work instead of five, and this will save him a term on the whole course The three parts of the final examination may be taken together or in any order Further information may be obtained from the Registrar, Apothecaries' Hall, Black Friars Lane, E C 4

The Apothecaries' Hall of Ireland grants the L A H, Dubl to students who pass the three professional examinations No changes have been made in the regulations, which can be obtained from the Registrar, 95, Merrion Square, Dublin

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom offer baccalaureate degrees in medicine and surgery, conferred on the results of examination

HIGHER QUALIFICATIONS

Those who have graduated in medicine and surgery are at liberty to seek higher qualifications if they wish

Doctor of Medicine and Master of Surgery

Graduates holding a bachelor's degrees can take the degree of Doctor of Medicine or Master of Surgery All the universities in Great Britain and Ireland confer such degrees The requirements vary and can be obtained from the different universities At the University of Durham the degree of Doctor of Surgery (D Ch) is offered in addition to degree of Master of Surgery (M S)

Master in the Science of Obstetrics and Master of Midwifery

The Irish universities grant the degree M A O The Society of Apothecaries of London offers Mastery of Midwifery (M M S A) The degree is given on the results of an examination, the requirements for which can be obtained from the Registrar, Apothecaries' Hall, Black Friars Lane, E C 4

MEMBERSHIP AND FELLOWSHIP

The Royal College of Physicians of London confers the Membership (M R C P) which is obtained by examination and the Fellowship (F R C P) which is an honorary distinction Medical graduates over the age of 23 are at liberty to enter for the Membership examination, details of which can be obtained from the Secretary, Royal College of Physicians, Pall Mall East, London, S W 1

Fellows are selected annually, from the ranks of members, by the council of the college

The Royal College of Surgeons of England grants a Fellowship to Members or to graduates of recognised universities who pass the primary and final F R C S examinations Candidates for the final examination who, owing to war work, have been unable to comply with the regulation that requires six months' residence as house surgeon in a recognised hospital may, if they can produce certificates showing comparable experience ther in the Services or in the EMS, apply for special onsideration There are no other war-time concessions n the regulations, copies of which may be obtained from he Director of Examinations, the Examination Hall, Queen Square, London, W C 1

Medical graduates who have been registered or eligible or registration, for at least three years may apply for xamination for Membership of the Royal College of Obstetricians and Gynæcologists (M R C O G) Pariculars of the regulations may be obtained from the Secretary, Royal College of Obstetricians and Gynæcologists, 58, Queen Anne Street, London, W 1

The Fellowship (F R C O G) is granted to Members who are judged to have advanced the science and art of obstetrics and gynæcology.

Graduates may become Members of the Royal College of Physicians of Edinburgh (M R C P E) on passing an examination, particulars of which may be obtained from the Secretary, 9, Queen Street, Edinburgh 2

The Fellows are selected annually from among the Members by the council of the college, and receive the degree of F R C P E

Fellowship of the Royal College of Surgeons of Edinburgh (F R C S E) is granted to medical graduates who pass the required examination, particulars of the regulations may be obtained from the Clerk of the College, Surgeons Hall, 18, Nicolson Street, Edinburgh

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a Fellowship which is registrable by the General Medical Council as an additional qualification (R F P S G). The candidate is examined in either medicine or surgery, as he chooses, and in an additional subject selected from a list of seventeen Those who pass the examination are eligible for election to Fellowship by ballot. The faculty may also elect without examination three candidates yearly who have been qualified at least twenty years, have reached the age of forty-five, and whose professional status is of a high order, and two others of high professional standing who have not reached the age of forty-five Details may be had from the Secretary to the Faculty 242 St Vincent Street Glasgow, C2

Membership of the Royal College of Physicians of Ireland (M R C P I) is granted on the result of an examination, the details of which may be obtained from the Registrar of the College, 6, Kildare Street, Dublin

Fellows are elected by ballot, and receive the degree of F R C P I

Graduates seeking the Fellowship of the Royal College of Surgeons in Ireland (F R C S I) must pass in two examinations, a primary in anatomy and physiology and a final in surgery Further particulars may be obtained from the Registrar, the Royal College of Surgeons in Ireland, Dublin

The Faculty of Radiologists offers a Fellowship (F.F R) to medical graduates of five years standing who have spent at least one year in general clinical work at an approved hospital, have practised radiology exclusively for three years and have held a radiological diploma for at least two years Candidates are required to pass an examination and submit a thesis Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery or pathology Full particulars may be obtained from the Warden, the Faculty of Radiologists, 32, Welbeck Street, London, W 1

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned

Public Health

A diploma in public health (D P H) is granted by the English and Scottish Conjoint Boards and, usually, by all the universities of the United Kingdom except Oxford, Cambridge and Sheffield The diplomas in public health usually granted by the Universities of Manchester and Bristol and the Irish Conjoint Board are at present in abeyance, and the D P H courses at the Universities of London, Birmingham, Bristol, Liverpool, Leeds, Aberdeen, St Andrews and Trinity College, Dublin, and the course at the London School of Hygiene and Tropical Medicine have been suspended The courses at Leeds and Durham will be held if sufficient candidates apply, and the Universities of Edinburgh, Glasgow, Belfast, and the three Colleges of the University of Ireland, at Dublin, Cork and Galway, are still holding courses; there is also a course at the Royal Institute of Public Health and Hygiene Durham, in addition to the diploma in public health offers the degree of bachelor of hygiene to medical graduates of any approved university who attend courses for part I of the examination at Durham; the degree of doctor of hygiene is conferred on those holding the B Hy who submit an approved thesis and pass in an oral examination

Psychological Medicine

The Universities of London, Durham Edinburgh, Dublin, Ireland (National University), Belfast (Queen's University), and the English and Irish Conjoint Boards grant diplomas in psychological medicine In addition to a D P M the University of London grants a diploma in psychology, taken chiefly by social workers, the course for which is being held at the London School of Hygiene and Tropical Medicine The courses and examinations for the diplomas usually granted by the Universities of Leeds and Manchester are at present suspended A D P M course is held annually at the Maudsley Hospital in the early months of the year Information can be obtained from the Honorary Director of the Medical School, Central Pathological Laboratory, West Park Hospital, Epsom, Surrey

Radiology

The Faculty of Radiologists grants a Fellowship (F.F R) which has already been mentioned The diploma of Cambridge (D M R E) will be discontinued after Oct 31, 1942 The Universities of London Liverpool and Edinburgh also grant diplomas (D M R) and the English Conjoint grants the D M R R C P & S Courses for the diploma at Liverpool University are at present suspended

Tropical Medicine

Liverpool University grants a diploma in tropical medicine (D T M) and tropical hygiene (D T H) and the University of Edinburgh and the English Conjoint Board each grant a diploma in tropical medicine and hygiene (D T M & H) Examinations for the English Conjoint D T M & H have been cancelled until further notice

Gynæcology and Obstetrics

The Royal College of Obstetricians and Gynæcologists grants a diploma (D R C O G) to practitioners who have had special postgraduate experience in obstetrics, they are required to submit case-records and commentaries, not less than 9 weeks and not more than 3 years before the date fixed for the examination. If these records are accepted the candidate is allowed to take the examination if not, he may be required to submit a new set of records or to modify the original set before he can be examined The University of Dublin also offers a diploma (D G O) for which a course is held at Trinity College and the Rotunda Hospital The degree of M M S A granted by the Society of Apothecaries of London has already been mentioned

Ophthalmology

Three examining bodies issue diplomas in ophthalmology—the University of Oxford (granting the D O), the English Conjoint Board (granting the D O M S) and the Irish Conjoint Board (granting the D O.M S R C.P and S I)

Laryngology and Otology

The English Conjoint Board offers a diploma (D L O.) for those who have made a special study of the ear, nose, pharynx and larynx

Anæsthetics

The English Conjoint Board also offers a diploma in anæsthetics (D A) Candidates must have special experience in giving anæsthetics The Irish Conjoint Board has also established a diploma in anæsthetics the first examination for which will be held next December

Child Health

Diplomas in child health (D C H) are granted by the English and Irish Conjoint Boards

Tuberculous Diseases

The University of Wales grants a diploma in tuberculous diseases (T D D) but courses of instruction are at present suspended

Bacteriology

Diplomas in bacteriology are ordinarily granted by the Universities of London and Manchester The course for the London University examination would normally be held at the London School of Hygiene and Tropical Medicine, but has been suspended during the war At Manchester both the course and the examination have been suspended

Clinical Pathology

The University of London offers a diploma in clinical pathology (D C P) A year's course of study is required

Dental Degrees and Diplomas

There are schools of dentistry at the universities of London Durham, Birmingham, Liverpool, Manchester, Leeds, Sheffield, Bristol, St Andrews Belfast and Dublin and at University Colleges of Dublin and Cork in the University of Ireland Leeds grants a diploma (L D S), a baccalaureate degree (B Ch D) and a mastership (M Ch D) London grants a B D S in addition to an L D S The University Colleges of Dublin and Cork grant a B D S and an M D S , and Trinity College, Dublin, offers a B Dent Sc and an M Dent Sc All the other universities mentioned offer L D S , B D S and M D S degrees , St Andrews offers a diploma in public dentistry (D P D) in addition

Licences in dentistry are also granted by the Royal Colleges of Surgeons of England and Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland

Candidates for the L D S of the Royal College of Surgeons of England are required to pass a preliminary examination in general education, and either the premedical examination in chemistry, physics and biology conducted by the Examining Board in England, or an examination accepted by the board as exempting from this examination The course lasts four years and must be taken at recognised dental schools and hospitals, but candidates who have completed not less than 6 months dental mechanics under a competent dental practitioner may be exempted from 3 of the 20 months instruction in this subject at the dental school Regulations and a calendar showing the dates of the examination may be obtained from the director of examinations, Examination Hall, Queen Square, London, W C 1

Candidates seeking the L D S of the Royal Faculty of Physicians and Surgeons of Glasgow must pass a preliminary examination in general education and another in scientific subjects (physics, chemistry and biology) The professional course lasts four years and must be taken at a recognised dental school There are three professional examinations, the first in human anatomy and physiology, the second in dental metallurgy and in dental mechanics, and the final, part I, in principles of medicine, surgery and therapeutics, general pathology and bacteriology , part II in dental anatomy, physiology, surgery, materia medica, orthodontics, radiology, pathology and bacteriology and operative dental surgery In addition to the L D S the Royal Faculty offers a higher dental diploma (H D D) to registered dentists who have practised for at least 12 months and who pass an examination in dental anatomy and physiology, dental surgery and dental pathology and bacteriology Information about both examinations may be obtained from the secretary to the Faculty, 242, St Vincent Street, Glasgow, C2

Regulations for the L D S of the Royal College of Surgeons in Ireland have been altered the course now lasts for 5 years, and up to the end of the fifth term lectures and examinations are the same as those for medical students taking the examinations of the Irish Conjoint Board In the sixth term dental students attend a dental hospital for an introductory course in dental mechanics, and in their third year they take the same course and examination in pathology as the medical students, and attend lectures and clinical courses at a general hospital in medicine and surgery, sitting for an examination in these subjects which of course differs from that of the medical students Their fourth and fifth years are spent entirely in the dental hospital Details may be obtained from the registrar, Royal College of Surgeons in Ireland, Dublin

THE NEW BMSA

THE medical students of this country sented for many years by a faculty the National Union of Students T had a chequered career but in spite has done good work on behalf of In 1940 the committee became Students Association but remained NUS At this time the BMSA re provincial medical schools, but thirteen London medical schools was requested by the Medical P draw up a report on the reform of and it became obvious that th fully representative Negotiat the schools not yet members of on what basis they would be After many discussions it was that would be most acceptab provincial medical schools woul dent organisation which might general student body through medical profession through the

The inaugural meeting of the the London headquarters of th 28 last, when 17 medical school were represented At the first tion was established and the co approved Forms of agreemen BMA were discussed and the empowered to put these on an

At the second session the im the association was discussed the reform of the medical curric by the end of September and a *to deal with this, and also to provi* views on organisation of the cou departmental committee on medical Ministry of Health has asked the

Most delegates were in favour of t *curriculum as a means of speeding* of doctors, and discussion mainly cen in which the available time could be speakers maintained that in view curriculum not only should experienc reserved from military service but the number of in most medical schools should be increased It w suggested that more use might be made of qualifi women as teachers All were anxious that full use should be made of the teaching material available in municipal hospitals To save time in the course, it was agreed that the long vacation should be abolished in favour of a fully organised fourth term, not merely a revision course, and the delegates wished staff and students to meet in consultation to discuss administration and teaching difficulties raised by shortening the course

Student health was considered In Edinburgh a special ward is open for all students (not medical students only) in which they receive free hospital care , and in addition a special students' insurance scheme has been established Students can register with one of five doctors, and on paying a fee of 10*s* 6*d* per annum become entitled to free medical attention Schemes for providing medical attention for students are also in operation in Cardiff and at Oxford Two delegates held that too much emphasis was being laid on the need of special health schemes for students, but the meeting as a whole considered that medical students, who can always get the very best attention for themselves, have a special responsibility in ensuring that other students have an adequate medical service A special subcommittee was elected to discuss this whole problem with the NUS

The feeling of the meeting was that during the present shortage of doctors more women should be encouraged to enter the medical profession It was pointed out that there are not enough places available in hospitals for the women who have already passed their second examination and that the problem facing these women is urgent At the same time it was realised that concessions obtained in the present emergency were likely to be taken back at the end of the war The meeting approved the principle of admitting women to all medical schools on equal terms with men

THE LANCET

LONDON SATURDAY, AUGUST 29, 1942

The Makings of a Doctor

A composite picture of many independent views expressed elsewhere in this issue

"THERE must be a better way of doing this," AITKEN suggests as a motto for his students "What is it ? Let's try something" Our recipe for making doctors has not worked badly in the past, but now that scientific knowledge has shot ahead of its application to life our medical training is revealed as full of holes There are plenty of excuses, the most notable being that seventy years are not enough to learn even a small subject thoroughly, let alone medicine SHAW has suggested that man should now repent and live to be three hundred, but however willingly we would oblige him we must wait for the endocrinologists to discover the elixir of life In the meantime by practising rigid economy we may be able to use the ordinary span of life and the six years of medical training to better advantage The first thing to realise about the curriculum is that by keeping things in we keep things out Some part or parts of the syllabus have got to dwindle to make room for new matter When it comes to dropping material from a curriculum there is always an outcry, at the outset of a journey it is far easier to decide what to take than what to leave out The present compression of the course as an emergency measure is taxing the wits of deans and vice-chancellors at this moment, they say—and rightly—that everything now taught in the curriculum serves some purpose in making the doctor Naturally Every addition to a man's knowledge helps to make him, and if a medical student studied subjects as remote from the curriculum as pyrotechnics and Sanskrit he would find they had a bearing on medicine, simply because all learning is a part of the same jig-saw It is our misfortune never to see it whole, we must do the best we can In the medical curriculum this surely consists in giving precedence to what is most important There is danger, of course, in being strictly utilitarian, foolishly applied, the principle would narrow the course instead of broadening it into a liberal education

We all agree that our aim is to make a good general practitioner, whose work is founded in scientific method and principle At present the premedical year is largely dedicated to acquirement of such method The preliminary subjects of botany, zoology, physics and chemistry have therefore to be studied in considerable detail, and in consequence the student loses perspective and sees them out of relation to medicine Is there any slack to be taken up here ? Some of the teachers think there is, they feel the time has come to drop botany from the curriculum and substitute a course in biological principles with a bias towards zoology, this might include too the relevant aspects of geology Some of the students think that inorganic chemistry and elementary physics should have been covered at school in the syllabus for higher leaving certificate In Germany before the war no serious attempt was made, it seems, to train the student in scientific method during his preliminary year, he did no practical work in biology or physics, though the chemistry course resembled ours No-one would charge the German medical profession with lack of scientific method, and it seems clear that the necessary experience can be acquired otherwise than through an overloaded and partly irrelevant premedical course There is even the disadvantage in our system that the premedical student may not be able to see the wood for the trees, anxious to satisfy the examiner in details he may overlook principles Nevertheless, method must be acquired sometime, and the earlier the better Is there place here for a practical fusion ? Could the beginner, for example, be introduced to the first principles of physics, as the Scottish students suggest, by way of a study of equipment which he will have to use later ? Suppose, after a simple "popular" explanation of the ophthalmoscope, he began a study of light and optics with a view to understanding how that instrument worked, or, after seeing the electrocardiograph in action, he turned his attention to electricity, and when he understood what he was about was taught to take a cardiogram ? The method savours of the highly practical system of Mr Squeers, but what could be better in medicine ? The boy who learned to spell "winder" and was then sent to wash it was getting just the sort of training the doctor needs In the same way inorganic chemistry could be approached through a study of drugs and poisons, beginning with what they could do to his patients the student would turn to considering where they fitted into the chemical groups and families There could be nothing narrowing about preliminary subjects taught in this way, on the contrary, the student would be constantly led to think of the wide field ahead of him, and would not always be fancying irrelevance in his immediate studies Now he is apt to call them "academic" (not leading to a decision OED), but it is a poor teacher that cannot illumine the student's path with his own vision of its distant goal

There are, indeed, plenty of opportunities for the teaching of scientific method at every stage in medicine, many of which are already well used By bringing the preliminary subjects into closer relationship with medicine as a whole there is little danger of robbing the student of needed experience This first year of the medical course cannot, in any case, be considered apart from ordinary school education, itself due for revision What is mathematics but training in scientific method ? And what should our school years give us but an outline of modern knowledge ? The old-fashioned method has always been to start the child with the elements and let him climb step by step to some understanding of his subject How much more interesting it is for him if he is given a simple picture of what is known about the subject and then is helped to fill in details This is the method advocated by the anatomy teacher who wishes students to begin their course by watching a rapid dissection of the whole body, of the zoologist who wishes them to understand man's place among vertebrates, grasping the principles of body mechanics, development and heredity rather than the detailed differences of species, of the teacher who wishes them to learn human anatomy and human physiology from a man with an understanding of their relation to medicine, so that there will be constant reference to those deviations from the normal which will be seen later in patients There is an increasing conviction, too, that the doctor must study the mind as well as the body that normal psychology must have its place with the study of anatomy and physiology, that psychiatry is one of the more important parts of general medicine Edinburgh has the distinction of being the first to recognise this to the extent of introducing a separate paper on psychiatry into the final examination Finally, the doctor's place in the social structure is becoming more important with the growing interest in preventive and social medicine, and here, it seems, we are short of teachers The establishment at other universities of chairs of social medicine like the one recently founded at Oxford should help to remedy this

No doubt teaching methods could be much improved in every subject, the cinematograph and the X ray deserve a much greater place in our medical schools, students learn more at tutorials than at systematic lectures, and one dean suggests that, since these are more easily arranged in a small school than a large one, more small teaching units should be established in hospitals now without medical schools Again, teaching in different schools appears to be uneven Thus the Scottish students ask for more chance to follow up fatal cases in the post-mortem room and laboratory, to give anæsthetics and to stitch wounds—*experience largely granted in many schools* Students south of the Border, on the other hand, lack the valuable opportunities for dispensary practice available in Scottish schools We must not however overlook the value of local colour and it would spoil one of the most effective stimuli in medical education if each school was not left some freedom to develop along its own lines This is the source alike of esprit de corps and of healthy emulation But whatever occupies the nearer foreground there can be no doubt, as AITKEN foresees, that doctors should take an increasing share in preventing preventable ill health, and they must be properly trained to do it The changes to come are thus a reorienting of the course towards the new demands which people are making on their medical services

AFTER THREE YEARS OF WAR

(*From* THE LANCET *of August* 25, 1917)

lasts for 5 years, and up to the end of the fif nore than
lectures and examinations are the same as those fo dent
medical students taking the examinations of the Irish Conjoint Board In the sixth term dental students attend a dental hospital for an introductory course in dental mechanics, and in their third year they take the same course and examination in pathology as the medical students, and attend lectures and clinical courses at a general hospital in medicine and surgery, sitting for an examination in these subjects which of course differs from that of the medical students Their fourth and fifth years are spent entirely in the dental hospital Details may be obtained from the registrar, Royal College of Surgeons in Ireland, Dublin

The Defence Services

THE Central Medical War Committee of the British Medical Association is responsible for the supply of all doctors for the defence services, and the Central Dental War Committee for the supply of dental surgeons

Royal Naval Medical Service

The usual regulations governing entry of medical and *dental officers to the Royal Naval Medical* Service are suspended during the war and the only medical officers being admitted are those granted temporary commissions in the Royal Naval Volunteer Reserve After the war any vacancies will probably be filled by selection of officers from among those who have served in the RNVR during the war There is still only one woman medical officer in the WRNS She holds the relative rank of a Surgeon Lieutenant, RNVR, and serves as medical superintendent attached to the WRNS headquarters at the Admiralty

Candidates for the Royal Naval Dental Service must be registered under the Medical or Dental Acts and must also have a registrable qualification in dental surgery The position respecting entry is similar to that existing for medical officers

Royal Army Medical Corps

No applications for regular commissions in the RAMC have been invited since the outbreak of war up to the present It is expected when recruitment for regular commissions is proposed, officers who served during the war will be considered first All war-time appointments are emergency commissions for the duration of the war, no short-service appointments are being made at present Recently qualified doctors wishing to be appointed to an emergency commission should apply to the secretary of the Central Medical War Committee at BMA House, or if resident in Scotland to the secretary of the Scottish Central Medical War Committee, 7, Drumsheugh Gardens, Edinburgh 3 Applicants should have held an appointment either as house-surgeon or house-physician for 6 months

Women medical practitioners are required for appointment to commissions in the Women's Forces for employment with the RAMC They are required mainly for general medical duties with the ATS A number have been selected for specialist duties Women must be under 46 and fit for general service Applications must be made through the Central Medical War Committee Applicants should have held an appointment either as house-surgeon or house-physician

ARMY DENTAL CORPS

No applications for regular commissions will be invited during the war, and it is expected that after the war any regular officers required will be made up at first from among those who have served as emergency commissioned officers No short-service appointments are being made at present, and all war-time appointments are for the duration of the war Recently qualified dental surgeons who wish to be appointed to an emergency commission in the ADC should apply to the Central Dental War Committee, 13, Hill Street, London, W 1, or if resident in Scotland to the Scottish Central War Committee, c/o the Department of Health for Scotland, Edinburgh, 1

Royal Air Force Medical Branch

Commissions in the medical branch of the RAF are now given only to those appointed to the Royal Air Force Volunteer Reserve for duration of the war Short service and permanent commissions are at present in

ome Guard

There were Home Guard medical officers, most of hom were also combatants, in the Home Guard from s start, but it was not until April 1941, that official ecognition was accorded to the Home Guard Medical ervice It now consists of a medical adviser at the Var Office, several zone medical advisers responsible or counties, cities, and parts of cities, numerous battalion nedical officers and still more numerous company medical fficers There should also be a medical orderly sergeant n each battalion and a corporal for each platoon, but generally speaking these non-commissioned officers have till to be appointed The services of medical officers are voluntary, they are appointed by commanding officers of battalions with the approval of the local medical war committee which has to be satisfied that their employment will not prejudice the efficiency of civilian medical services It is now widely recognised that the exigencies of invasion might in any case prejudice the efficiency of the civilian services and the approval of the local medical war committee is usually given as a matter of routine The duties of HG medical officers were defined afresh in April, 1942, and are now as follows to act as medical advisers to zone, battalion and company commanders, to give or arrange for lectures on first-aid and hygiene for *all* HG personnel, to train stretcher bearers and medical orderlies, or to arrange for their training by Army medical, ARP or voluntary aid authorities, to carry out such medical examinations of personnel as may be necessary, to make arrangements for evacuation of casualties, to organise casualty collecting posts which should normally be on a basis of not less than one per platoon The interpretation of these duties varies somewhat in different areas but it is of the first importance that MOs should see that every man in the Home Guard knows as much as possible about how to help his wounded comrade, and that he should be able to count upon finding a casualty collecting post within walking distance, no matter in what area he may happen to be wounded In other words, the HGMS must anticipate conditions in which ambulance traffic is impossible and the wounded will have to depend on strictly local assistance

When it comes to examining those who claim to be unfit for service in the Home Guard, the MO has the assistance of certain definite rules, but in this as in other spheres he will do well to remember the words of General Wavell "The general who allows himself to be bound and hampered by regulations is unlikely to win a battle" MOs are likely to be asked by commanding officers what they ought to do about old soldiers who can be of great use in guard and other duties not calling for great mobility although they are technically unfit for HG service owing to some disability, such as lameness The best advice in such cases is that which helps to maintain the morale and defensive powers of the Home Guard

An important duty of MOs is that of keeping in touch with local authorities These authorities have recently been instructed to set up miniature aid posts in private houses These posts are the civilian counterpart of the HG casualty collecting post, and both alike will have to cater for every sort of casualty that may come within their range, whether military, civilian or HG In order to avoid wasteful overlapping, cooperation with the local authority is essential and in many areas a conjoint committee of local authority, HG WVS, and Red Cross representatives has been formed to deal with the whole question The HG medical officer is expected during invasion to allow first claim on his services to any aid post or hospital in whose service he may chance to be If he cannot reach the aid post or hospital, or is not needed there, he is at liberty to report to his battalion headquarters, which means that he will come under the orders of the battalion commander, and will in effect be mustered But there is great official objection to the compulsory mustering of HG medical officers and it is only allowable in very rare instances This may seem to involve a distinction without a difference, but the distinction might prove important if the MO were wounded or killed in the course of his HG duties Whether mustered or not, the Home Guard MO is entitled to wear his uniform (which will be that of a major if he is a battalion medical officer) at all times when he is liable for HG duties This liability would appear to begin when he enrols in the Home Guard but in actual practice uniform is only worn when on duty or in immediate expectation of being called upon for HG duty The uniform is issued without charge and consists of the ordinary battle dress with a Red Cross brassard which may possibly (not certainly) serve as some protection in action The Home Guard MO may not appear to have very extensive duties but when the time comes the battalion or company whose MO has built up an efficient medical service will show higher morale and better capacity for fighting than that in which the MO has not brought real enthusiasm to his job

Health Services at Home

EMERGENCY MEDICAL SERVICE

The medical schools have responded to the suggestion of the General Medical Council that the course should be shortened where this could be done without loss of standard, with the result that unusual numbers of candidates sat for their finals this summer and many more qualified than last year Many of these new members of the profession will be serving in the EMS during their first six months of practice—valuable experience, since the EMS is consolidating into the foundation on which a unified hospital service will be built after the war

The Ministry of Health announcement (circ 2660) that the rate of recruitment of doctors to the Forces will be speeded up during the next few months has changed the prospects of newly qualified men in some ways Thus, until further notice, all men who are fit for military service and who hold A posts in hospitals (junior whole-time resident posts for which no previous experience is required) will be recruited at the end of their six months period of office in the post Men holding B2 posts (junior whole-time posts, not necessarily resident, for which previous experience is required) will also, if fit for service, be recruited at the end of six months Since it will no longer be possible to fill B2 posts by men who have just come to the end of an A appointment B2 posts will in future be filled by women, or by men unfit for military service or foreign doctors Unmarried women doctors under 31, however, may now be compulsorily recruited on the plan which, up to now, held for men thus before recruitment they will be able to take a B2 post after six months in an A post, and a B1 post after six months in a B2 post Thanks to the large numbers of men and women qualifying and the system of appointing final-year students as residents, there is not likely to be any shortage of house officers this year

The Forces need other personnel besides the newly qualified, and their increasing demands have influenced developments in the EMS during the year They have first claim on all medical men under 46, so that the EMS is having to consider carefully the distribution of its medical staff and especially of the consultants and specialists remaining to it. The Medical Personnel (Priority) Committee scrutinises the needs of the Fighting Services and has been able to suggest ways of economising so that their demands can be lowered to some extent. Regional committees have also been set up to see that there is no overlapping, and that wherever possible the doctors of one Service will undertake work for another. More use is being made of civilian doctors, too, and plans have been devised for moving medical and nursing staff from hospital to hospital as their services are needed. A list of EMS hospitals has been drawn up at which Service cases will be concentrated, and staff will be correspondingly grouped to meet their needs. Committees have also been appointed to economise the use of specialist staff in ear, nose and throat work and psychiatry.

Other aspects of the EMS have not been neglected. The pathological laboratories have been increased in number since last year and now form a network supplying the greater part of the country; the laboratories are being linked up with the universities and will certainly become a permanent and valued part of English medicine. The EMS transfusion scheme has been expanded and consolidated and is pulling well with the Service schemes. EMS hospitals are trying to relieve the waiting-lists at voluntary hospitals, whether under the scheme or not, by offering facilities for the transfer of patients; EMS hospitals will now be able, for example, to accept gynæcological cases. Rehabilitation schemes for patients with head injuries or orthopædic conditions have been developed, and new centres for the treatment of spinal injuries have been formed. Students have access to these as well as to the other special centres for plastic surgery and jaw injuries, head injuries, chest injuries, peripheral nerve injuries, orthopædic surgery, fractures, and skin diseases. There are also special centres for neuroses, to which students are not given access. Interchange of knowledge through the committees of the Medical Research Council is as lively as ever, and new committees on spinal and crush injuries have been formed. The EMS is giving up some of its convalescent centres to provide hostels for ATS and nurses, or to be used as residential nurseries; it is understood that if casualties became heavy the centres would revert to their original purpose.

Salaries have not been revised since last year, and are paid on the following scale:

		£
Group officer		1300
Officer in charge of surgical or medical division (hospital of 500 beds and over)		950
Surgeon or physician specialist		800
Medical officers	Senior	550
	Junior	350
House officers	Senior	200
	Junior	120

The future of the service is already under consideration; surveyors are working on plans for a national hospital scheme which will certainly be organised regionally, though not necessarily according to existing regions, and will probably be administered through the local authorities.

INDUSTRIAL MEDICAL SERVICES

The effect of occupation on health is a subject which has become increasingly popular during the past twenty years or so, and partly owing to the stimulus of war, but partly also to other causes, industrial medicine at the present time is in a state of transition. Whatever direction the changes may take, it seems clear that industrial or occupational medicine in the future will provide more and more opportunities for medical men and women. Industrial health is at present supervised by a number of departments or organisations, the oldest of which is the Factory Department of the Home Office, recently transferred to the Ministry of Labour, which administers the Factories Act, the many regulations and welfare orders dealing with the prevention of accidents and illness, the regulation of the hours of work of women and young people, and the provision of cloakrooms, washing accommodation, first-aid and ambulance rooms, mess-rooms and canteens. On the staff are 15 whole-time medical inspectors of factories whose work largely consists of general and detailed investigations of any conditions which may affect the health and welfare of factory workers. Under their supervision some 1700 general practitioners render part-time service as examining factory surgeons, and their main duties are the medical examination of all young entrants into industry, the periodical examination of workers engaged in certain unhealthy processes, and the issuing of certificates under the Workmen's Compensation Acts for the scheduled industrial diseases. Health in coalmines is dealt with by a medical inspector of mines, and it seems likely that under the new Ministry of Fuel and Power the medical services for coalminers will be extended and more whole-time doctors appointed. The silicosis and asbestosis medical board is made up of 9 whole time medical men whose function is to examine workers entering silicosis- and asbestosis-producing industries, to carry out periodical medical examinations of these workers, and to issue certificates for compensation in cases who have actually contracted silicosis or asbestosis.

Before the war the practice of appointing whole time or even part-time medical officers to individual factories had not been adopted in this country as widely as it had been in the United States of America. But there was a nucleus of about 50 whole-time works medical officers in various factories throughout England, Scotland and Wales. Partly as a result of the Factories (Medical and Welfare Services) Order, 1940, made by the Minister of Labour, there has been a rapid increase in the number of whole-time and part-time medical officers in factories. The Ministry of Supply has also appointed a number of whole-time doctors to work in the Royal Ordnance Factories scattered throughout the country. The Minister of Labour's Order applies only to factories doing work on behalf of the Crown and is essentially a war time measure. It is probable however that many of the appointments will become permanent after the war because it is a matter of common knowledge that once employers have experienced the benefits that a medical service can contribute to the smooth working of a factory—and incidentally to the balance-sheets—they rarely abolish it. The medical officer in a factory will find a wide field to interest him and great opportunities for studying the reaction of the workers to their environment. Apart from day-to-day examination of individuals who are sick or exposed to special risks, the doctor can undertake the personal and general education of the workers in hygiene, and can promote effective liaison between the factory services and the general medical and hospital services. He can supervise the treatment of accidents, reduce the number of septic cases to a minimum, follow up the treatment of fractures and other serious injuries and illnesses, and see that all patients return to work in the shortest possible time consistent with adequate treatment and rehabilitation. He can treat cases of minor illness and injury in such a way that many of them will be able to remain at work. In war-time accidents and illnesses which keep workers, especially skilled men, away from the factory must be regarded as war casualties and a medical officer who can minimise the resulting loss of working time is doing highly important war work.

Facilities for training potential and newly appointed works doctors have been provided by week-end courses in London, Birmingham, Manchester, Sheffield and Leeds. Research work into environmental conditions in factories has been carried on during and since the last war by the Industrial Health Research Board under the Medical Research Council, and much valuable physiological and statistical work has been done. The council has recently appointed a director of industrial medical research and further important developments on this aspect of industrial health can confidently be expected.

PUBLIC HEALTH

The protection of the public health has now been a recognised function of the state and local authorities of this country for almost a hundred years. Originally concerned with problems of sanitation and environmental hygiene, the British public health service led the world during the nineteenth century in providing sanitary necessities and in removing some of the worst effects of the industrial revolution. About the beginning of this century its scope was extended to the more personal side of public health with the creation of the school medical, maternity and child welfare, tuberculosis and venereal disease services and all their ancillaries, and later the Local Government Act of 1929 enabled local authorities to take over and improve a vast system of public hospitals, so that at the outbreak of war the beds controlled by public bodies were more than twice the number of those in voluntary hospitals To the man or woman seeking a hospital or laboratory appointment the differences between service under a local authority or the Emergency Medical Service and in a voluntary hospital are slight and diminishing

These considerations, however, hardly apply to the student contemplating public health as a specialist career No medical officer of health may be appointed unless he holds a registered diploma in public health or its equivalent, but once accepted he enjoys security of tenure, in that his removal—like his appointment—must receive the sanction of the Minister of Health Since the war the number of institutions at which the course of training required for the diploma in public health is available has been limited After obtaining the DPH, an appointment as assistant medical officer of health and school medical officer can, under present conditions, be obtained without difficulty The duties at this stage are mainly clinical, in connexion with the school medical service, maternity and child welfare and specialised clinics of various kinds, or in charge of beds in isolation hospitals In the counties, the post of assistant medical officer of health is often combined with that of medical officer of health of a county district, which provides an attractive mixture of administrative and public health work The higher posts are in the main administrative and the medical officer of health of, say, a large county borough, is more in the position of the managing director of an important firm employing several hundreds of technicians than a doctor The ever-increasing emphasis on preventive medicine enhances the importance and scope of the work of public health departments and medical officers of health

On the one hand the war has brought new problems and laid fresh tasks on the public health services, while on the other it has seriously reduced the personnel available to carry out these tasks Recruitment is not only thinning at an ever-increasing rate the ranks of medical officers of health and their assistants, but has taken a heavy toll of essential auxiliaries such as sanitary inspectors, health visitors, and clerical officers Among the new problems may be mentioned the evacuation of children and others to safe areas, which has thrown a strain on the public health staff and sanitary resources of many rural districts and made necessary the extension of schemes for sewerage and water-supply, the establishment of temporary hospitals, sick bays and hostels for maternity cases and minor infectious diseases and the expansion of the services already existing, the improvement and supervision of the hygiene of air-raid shelters used as dormitories in target areas, and cooperation with the medical departments of the Forces in matters common to them and the civilian population, such as epidemic outbreaks, accommodation of infectious cases, water-supply and sewage disposal in camps There has also been a large expansion of laboratory facilities under the Ministry of Health's emergency laboratory service, this has put at the disposal of every local authority and EMS hospital a laboratory capable of meeting its needs Much thought has been given to the planning of the medical services after the war and already public pronouncements have foreshadowed a regional hospital organisation in which voluntary and public hospitals will both be included, graded, and integrated Whatever the future may bring it is clear that there will be drastic changes, and that preventive and social medicine will play a larger, not a smaller, part in the whole scheme

LONDON COUNTY COUNCIL HOSPITALS

The hospitals service of the London County Council provides not only special facilities for undergraduate instruction, but also opportunities for valuable experience for medical graduates who intend either to be general practitioners or consultants, or to make the LCC Public Health and Hospital Service their career At the beginning of the war, the service, one of the most comprehensive hospital services in the world, contained 97 hospitals with beds for 71,694 patients The 97 hospitals consist of 44 general hospitals, 32 special hospitals and 21 mental hospitals and institutions for the mentally defective; 54 of the hospitals are included in the Emergency Hospital Scheme

Treatment is provided in these hospitals for all kinds of acute and chronic illnesses, including fevers, tuberculosis, mental and nervous disorders

HOSPITALS BRANCH

Medical superintendents of the hospitals, who are expected to be experienced hospital administrators, receive £850 to £1650 a year, in hospitals varying in accommodation from 160 to 1300 patients In addition, medical superintendents are provided with an unfurnished house or quarters with payment by the Council of local and water rates The other full-time medical staff are classified as follows

Grade	*Annual salary*
Deputy medical superintendent, class I	£650—£50—£800
Deputy medical superintendent, class II	£600—£30—£750
Deputy medical superintendent, class III	£550—£25—£650
Deputy medical superintendent, class IV	£500—£25—£600
Senior resident surgeon physician, or obstetrician, and senior assistant medical officer	£500—£25—£600
Assistant medical officer, class I	£350—£25—£425
Assistant medical officer, class II	£250
Senior house officers	£200
House physicians and house surgeons	£120

These officers are provided with board, lodging and washing Clinical assistants, who are non-resident, receive £150 a year with meals when on duty Vacancies in the higher grades are filled as far as possible by promotion from the existing staff In addition, a large number of part-time consultants and specialists are employed in the various hospitals and the establishment provides for a certain number of whole-time non-resident specialists at a salary of £1250—£50—£1500

There was some disorganisation of the consultant service at the outbreak of war, but by February, 1940, it was again working normally, though with reduced numbers of sessions A comprehensive pathological service has been established There are seven group laboratories, each of which serves a number of hospitals, a central histological laboratory, and an antitoxin establishment Attached to the group laboratories are subsidiary laboratories situated in the various hospitals Normally a medical staff of 27 is attached to these laboratories, but some of them are at present working at other laboratories under the EMS

TEACHING FACILITIES

During the war, courses in fevers for the diploma in public health are held in the council's hospitals, other post-graduate facilities have remained as they were The British Postgraduate Medical School is located in the Council's Hammersmith Hospital

Patients under treatment in the Council's hospitals have not been much reduced in number, and increased use is being made of them for teaching purposes Maternity wards of many of the voluntary hospitals have been closed, and arrangements have been made whereby maternity students have had training and experience in the maternity departments of the Council's general hospitals Most of the students are resident and attend for a fortnight at a time In addition, students have been allocated to a number of the general and special hospitals under the Emergency Hospital Scheme to act as dressers The Council has agreed that medical training and experience shall be provided whenever possible, in most cases the students, some of whom are resident, receive systematic instruction from the resident medical staff of the hospital The fever hospitals provide special facilities for undergraduate instruction, and when patients are available, for demonstrations in the diagnosis and treatment of smallpox for both undergraduate and postgraduate students Students are resident during their course of instruction in some of the fever hospitals

Most of the general hospitals are recognised training centres for candidates for the University of London MD examination, 18 of them for the Diploma and Membership of the Royal College of Obstetricians and Gynæcologists and for the final FRCS examination and the Diploma in Anæsthetics Service at Queen Mary's Hospital for Children, Carshalton, is recognised by the Royal Colleges of Physicians and Surgeons as a part qualification for the Diploma in Child Health

MENTAL HOSPITALS BRANCH

The mental health services of the LCC are responsible for a large medical service, vacancies in which are normally advertised at short intervals No new permanent appointments are being made at present, indeed the staffs of the various hospitals have been reduced as a war measure In peace-time those appointed to the service may be sent to any of the Council's mental hospitals and may be transferred from one hospital to another should circumstances require it An applicant enters the service as assistant medical officer at a salary of £470 a year, rising by annual increments of £25 to £570 Salaries are graded through the various ranks to £1450 paid to superintendents of large hospitals, a superintendent is also provided with an unfurnished house on the hospital premises Assistant medical officers may be required to live in the institution which they are serving and to pay fixed rates for board, lodging and washing Officers contribute to a superannuation fund They are required to take a Diploma in Psychological Medicine within three years of entering the service and the diploma carries with it a payment, in addition to salary, of £50 a year Promotion is reasonably rapid for men The mental health services are actively concerned in the EMS Three hospitals are used entirely as emergency hospitals and at eight others there is an emergency hospital section Treatment is provided for all types of acute, medical and surgical cases and the hospitals are staffed and equipped to give specialised treatment The medical staff for these hospitals is drawn mainly from the emergency medical service

MENTAL HOSPITALS OUTSIDE THE LONDON AREA

Posts for medical officers in the provinces are similar in scope and remuneration to those in London They are advertised regularly in the medical journals

PRISONS

At the larger prisons whole-time officers are appointed, sometimes with deputy medical officers to assist them Unfurnished quarters are provided or an allowance made in aid of rent Posts are pensionable and promotions are made as vacancies occur Candidates with a diploma in psychological medicine receive £50 per annum more on appointment than candidates without this qualification, and are given preference provided they also have good all-round general experience At the smaller prisons no whole-time officers are employed local practitioners are usually appointed as part-time officers Further particulars can be obtained from the Prison Commissioners, Oriel College, Oxford.

Services Abroad

INDIAN MEDICAL SERVICE

Recruitment to the Indian Medical Service, which is designed primarily to meet the needs of the Indian Army, has been modified by the war, and officers are now appointed to emergency commissions in the military branch for the duration of the war The method of recruitment of male medical officers, other than those of Indian or Dominions origin, has recently been altered and those wishing to be appointed are required to join the Royal Army Medical Corps first After a course of instruction, they can apply to be posted to the Indian establishment, and are then given an opportunity to transfer to the Indian Medical Service Officers selected for transfer will be given preference when the permanent commissions in the Indian Medical Service are granted again after the war The upper age-limit for European emergency commissioned officers is at present 45 Antedating, in the Indian Medical Service, may be granted on transfer to officers who have held an approved whole-time appointment in a recognised civil hospital and to those who possess higher qualifications and professional experience Antedating equivalent to half the period spent in practice less the period granted in respect of hospital appointments, is also allowed up to a maximum of 5 years All previous full-pay commissioned service with the armed forces as a medical officer also counts towards rank and seniority on transfer. Qualified officers selected for specialist posts are granted appropriate temporary rank with the pay and allowances of the appointment Passages to India are not granted to wives and families but if, on the termination of his service, an emergency commissioned officer chooses to stay in India, an allowance is made to take him and his family to the place they choose to live in

The pay of a European lieutenant in India is £585 per annum and of a captain on promotion £750 per annum, on his release an emergency commissioned officer receives a minimum gratuity of Rs 2000 if his date of registration as a doctor was before Jan 1, 1940 or Rs 1000 if registered on or after that date, provided he completes a year of service, he gets an addition of a month's pay for each further year of Army service If invalided out for a disability due to service he receives disability retired pay appropriate to his rank and degree of disablement, which for Europeans is as for officers of the RAMC If he dies as a result of military service during the war provision is made for his widow and children

Women medical officers are appointed direct to the Indian Medical Service by the Secretary of State for India under conditions similar to the above Full information regarding these appointments and those available for Indian medical officers, for whom the age limit is 40, may be obtained from the Secretary, Military Department, India Office, 4, Central Buildings, London, S W 1

WOMEN'S MEDICAL SERVICE FOR INDIA

Admission to the service is by selection in India and England The cadre consists of 44 permanent and 6–10 temporary medical officers Appointment is open to English and Indian qualified women Vacancies are few—usually only 3 or 4 in each year, and there is little recruitment from England There is also a training reserve of about 14 recently qualified women recruited from Indian universities Since the outbreak of war no members of the training reserve have been sent to England for postgraduate study Leave out of India has also been restricted and vacancies in the service are being filled by doctors in India as need arises The office of the Dufferin Association in London is closed for the duration of the war, and the post of medical adviser is in abeyance Those seeking information about the Association should apply to the High Commissioner for India, India House, Aldwych, London, W C 2

During the war women medical officers are appointed direct to emergency commissions in the Indian Medical Service by the Secretary of State for India, under conditions similar to those for men Full information may be obtained from the Secretary, Military Department, India Office, Clarence House, 4, Central Buildings, London, S W 1, or from the Medical Adviser to the Secretary of State, India Office, S W 1

COLONIAL MEDICAL SERVICE

The Colonial Office is anxious that young doctors should realise that recruitment for the Colonial Medical Service at the present time has been officially approved and that service in the Colonial Empire is of as much national importance as service in the Forces Vacancies occur most often in the larger medical departments in tropical Africa Specialist appointments are usually reserved for officers already in the service who have shown outstanding merit in a particular branch Vacancies may arise for women with experience in maternity and child welfare work Selected candidates are generally required to attend a course in tropical medicine and hygiene, before going overseas or during their first leave period The various government medical departments employ about 700 European medical officers, including some 30 women, and about 1200 locally appointed medical officers Medical experience may include—among other diseases associated with the tropics—malaria, yaws, leprosy, sleeping sickness, plague, yellow fever and cholera, as well as the diseases of common medical practice An officer in the Colonial Medical Service has special opportunities for the practice of his profession in preventive medicine as well as in other branches, there are also opportunities for teaching and research Full particulars of the terms and conditions of service may be obtained from the Director of Recruitment (Colonial Service), Colonial Office, 2, Park Street, London, W 1

SUDAN MEDICAL SERVICE

This service is responsible for carrying out civil medical and public health duties in the Anglo-Egyptian Sudan and for the health of the Sudan Defence Force The British staff consists, at present, of 34 medical inspectors and senior medical inspectors with 11 additional senior posts promotion to which is by selection Medical inspectors are first appointed on probation for two years Pay starts at £E720 (approximately £738), rises by biennial increases to £E1080 and after 13 years service to £E1200 (approximately £1230) There are higher scales of pay for the senior posts No income-tax is at present levied in the Sudan There is a pension and provident fund An official qualifies for pension at the age of 48 if he has then completed at least fifteen years service and retirement is usually enforced at 50 There is provision in the pension scheme for widows and children The service offers a great variety of work among many different races, including work in large and well-equipped central hospitals, supervision of medical and public health work in the towns and districts, inspection of schools and school-children, examination of candidates for government service and the training of medical assistants and Sudanese sanitary officers and overseers The Khartoum Medical School is staffed by members of the service who receive additional remuneration for this work Private practice is allowed so long as it does not interfere with government duties but there are opportunities for such practice only in a few of the larger towns In peace-time, leave of 90 days is usually granted every year after the first 18 months of service, and study leave may be given for special purposes Full pay is drawn during leave periods and there are allowances towards the cost of passages Since the war the service has had to undertake many additional responsibilities Nearly half of its members have been given temporary commissions and a number have found that their duties have carried them into adjacent territories Recruitment ceased for a time at the end of 1939, but has since been revived The Central Medical War Committee is fully aware of the requirements of the service and has raised no objection to the appointment of those selected to fill vacancies Further information may be obtained from the Consulting Physician to the Sudan Government, 93, Harley Street, London, W 1

SOUTHERN RHODESIAN MEDICAL SERVICE

The government of Southern Rhodesia maintains a medical and public health service in which there are 16 whole-time appointments and 34 part-time appointments The part-time government medical officers are usually in general practice and serve all stations except the large towns of Salisbury and Bulawayo There are also 9 medical officers who receive a subsidy of £250–£360 a year for doing necessary government work, most of these are medical officers to mines or medical missionaries Rates of pay for whole-time officers are as follows

Medical director chief health officer, and director of medical services	£1500 p a
rising by £50 increments to	£1750 p a
Director of laboratories (2 posts)	£1000 p a rising by £50 increments to £1250 p a
Radiologist (2 posts)	
Medical superintendent of mental hospital	
Field officer	
Health officer	
Male school medical officer	
Female school medical officer	£600 p a
rising by £25 increments to	£900 p a
Medical officers to leprosy or mental hospitals (3 posts)	£600 p a
rising by £25 increments to	£750 p a

Government part-time medical officers are appointed at a salary of £600 p a rising by £25 increments to £750 p a Promotions are made as vacancies occur to posts which carry a final salary of £900 p a Officers usually find that practice offers an additional source of income ranging from £200 p a upwards Their government duties include the supervision of the 18 government hospitals and numerous native clinics, and of gaols, police camps and government stations Leave is granted at the rate of one-eighth of service, and may be taken in periods not exceeding 184 days at a time; study leave is also granted After two years' service medical officers under 45 can be appointed to the fixed establishment and contribute to a pension scheme, the retiring age being 60 The service has released many

officers to serve in the Forces, and additional calls have been made on the remaining medical personnel since the department took over the hospital care of a large air training group in the colony, as well as the supervision of the several camps of interned Italian civilians Appointments in Great Britain to the Services are made by the High Commissioner for Southern Rhodesia, Rhodesia House, 429, Strand, London, W C 2, who will supply details on request.

In the New World

Twenty-five fortunati accepted last year the invitation of the Rockefeller Foundation to continue their medical studies at American and Canadian universities Thirteen of them have told us of their experiences Their hosts should be able to judge, from the manner of the telling, how much their generous welcome has been appreciated

* * *

Ships, like cities, sometimes come alive London before I left was alive, and our little ship came alive half way through the journey At first there were long lines of little ships on a silent sea, looking like a scene from the child's jigsaw puzzle, then one night the wind rose to a full gale, the sea became the Atlantic, the ship an animal fighting for survival I remember spending the greater part of the night on the covered-in deck below the bridge Our funnel was on fire and illuminated most of the ship in patches, and a bit of the sea around The log was hanging vertically downwards sometimes with only a few yards of the cable showing above the waves, sometimes stretching down into the bottom of a gigantic trough We seemed to be rolling clean over on to our side, and despite the fact that we drew only twelve feet of water (having no cargo except a hogshead of whisky) some of the waves came overboard and one caught the bridge Judging from the inclination of the mast to a hypothetical vertical, we never leaned over more than about 20°, but it felt like 45° at least Down in the cabins everything was flung against the starboard wall—carpet, clothes chairs washing things, even the bedcovers—and my dumpy little "War and Peace" leaped from the top bunk and landed square on my partner's chest as he wrestled with the furniture at the opposite side of the cabin A few days later we arrived in America, admired the myriads of identical, unreal churches along the banks of the St Lawrence, made acquaintance with the comforts and the negro conductors of the Pullmans, goggled frowsily at New York and the Skyway and arrived at our destination just after the dean of the medical school had left So we barged into the nearest office we could see and explained our plight to an elderly unassuming gentleman, who seemed to understand not only our accents but us as well This was no problem to him at all · within five minutes he had asked us home for dinner and the night, rung up his wife, and gone out with us to buy—miracle of miracles—a steak over the counter Later we discovered he was one of the foremost experimental physiologists in the world That incident was illustrative of American hospitality

In a general way the work here is much the same as at home At first we were overwhelmed by the multitude of lectures and exams and the dimensions of the text-books Certainly one is expected to learn more than at the English medical schools, but the result tends to be that one thinks less Lectures are given, the textbook is read by the few who can plough through it in time, and frequent questions are asked on the material The Americans have a popular radio programme called "Information Please" run on the same lines as our Brains Trust, but instead of having a discussion, the participants simply answer questions, right or wrong, for a bet with the questioner That's another illustration of American life In the medical education sphere, the result of this method is the turning out of a high level of general practitioner, who knows what to do in most circumstances according to Mrs Beeton, but who tends, I feel, to lose sight of the humanity of his patient, it also accounts for the purely bandwagon research in the more specialised journals But with these faults, the education is still at least as good as that in England, which after all suffers from the same malady, and, aside from medicine, opportunities are great In the last months I have heard Toscanini, Heifetz, Rachmaninoff and Horowitz, and have seen a production of Macbeth that left as little to be desired as any production could, I have driven to Chicago and back and seen something of the little towns that go to make the Mid West, without realising that it was as if I had been from London to Warsaw in two days, I have acquired an old blue jalopy which rears at a traffic light like a bustled suffragette, I have grown fat eating irradiated oats, polyvitamin chocolate bars and aseptic hot dogs, I have almost essayed to jitterbug but find the cut of English trousers rather a handicap, I have shouted at football games but still can't fathom why, I have made many friends, both students and faculty, in my own and other universities, I have got engaged to be married I like America

* * *

War is best known to some of us in its guises of rationing and ARP The United States of September, 1941, was a country on the brink of war, and preparing for it, but a country where ARP was still a strange new creature and rationing an almost unthinkable innovation These two aspects were incongruously blended on the ship which took twelve of us to America Big pats of Canadian butter and such strange dishes as "head cheese" convinced us we were no longer at home, but the ceaseless watch for the enemy, the dashing naval escorts and the numberless other evidences of the Battle of the Atlantic, still reminded us of Britain And when we landed, despite the great generosity and hospitality of our hosts, some of us continued to feel sojourners in a strange land until Pearl Harbour was bombed three months later The medical profession at least can take credit for being partially prepared in a military sense and well prepared mentally Within a few weeks of the declaration of war, many hospitals had sent large military or naval units to training camps, and in some cases to war zones, and only a few days elapsed before plans were being made for an acceleration of the medical course to reduce by a year the time taken to graduate

American medical students are recruited from college graduates who have spent four years in studying premedical subjects and the liberal arts For this reason the American medical student is usually twenty-five or over before he is qualified and can take an interneship, which corresponds to our residentship For the duration of the war, the colleges as well as the medical schools have shortened their courses from four to three years by running classes throughout the long summer vacations Recently, too, it has been made possible in some universities to fuse the final year at college with the first at medical school One aspect had to be seriously considered in the acceleration of college and medical school courses most students pay for their classes in part by working—during the term, for instance, they may act as first-aid workers in factories or as waiters in restaurants, on a part-time basis Their main income, however, is derived from the work they do during the long vacation This source has been suddenly and unexpectedly cut off, but the Bureaus of Education and of the Budget are preparing a bill to lay before Congress designed to provide government loans for those students who need them Interneships are offered by most hospitals for twelvemonth periods, but now that the academic year has been reduced to nine months interneships may be reduced accordingly Many American hospitals provide "rotating" interneships giving experience in several departments for short periods These may prove valuable for those who have only a relatively short interval between graduation and induction into the Army Interneships hold an important place in medical teaching, at least some of the clinical instruction that British doctors receive at university their American counterparts derive from interneships Thus doctors in America tend to go into practice several years later than in Britain, they are often married and usually have little money left after their long training Fortunately for the young doctor, it is the custom for him to set up his plate, or "shingle" and build up a practice of his own, in the Middle West at least the custom of buying a practice is almost unknown The age of the students and the fact that they are already graduates of a premedical college tend to remove the medical school from contact with other parts of the university and to give it a position resembling in some respects that of a technical school The American doctor has a sentimental niche in his heart for his college, which his medical school never seems to share He is much more interested in learning his profession than in anything else, and he brings to this that keenness and earnestness that are a feature of the American character Scholarships to medical school, such as ours at home, are rare, financially their place is taken by external jobs Another type of scholarship is fairly common, however one which provides the student with a year free from classes and examinations, in which to do research under one of his professors Research is in general more closely woven into the medical teaching here than at home and the interest of the students is correspondingly increased in it While the benefits from this state of affairs are great, it is one of the reasons why some of the clinical work is left to the interneship

* * *

Among the achievements of American medical schools the one that impresses me most is the close liaison between medical practice and medical research, an association which has been so productive in recent years The correlation between preclinical teaching and its clinical applications too stimulates interest There are differences in medical teaching not only between the United States and Britain but between different schools in the USA A few schools regard lectures as desirable only when there is no adequate literature on the subject, student research is encouraged, and the aim is not so much the acquisition of facts as the development of a truly scientific approach to medicine Exams are rare, but are the cause of a good many "fatalities" It is considered that students who survive and do well in such a school will continue to succeed later in their medical career The other and more common type of medical school has highly organised teaching, many excellent lectures and clinical demonstrations, plenty of minor exams and a few large ones Students are carefully graded on the results of these exams and on the reports of their instructors about their practical approach to patients In this way the average standard is maintained at a high level, and there is inevitably a competitive spirit among the students In a few cases this may restrict a student's learning, since the temptation is to work for the next exam and to study only those things on which questions are expected The exams are interesting and different from those I am used to Many of them are of the one-word answer type and also of the "true" or "false" intelligence test variety With well thought-out questions this type of exam is efficient in assessing a student's knowledge in a minimum of time, and it is easy to express the result on a numerical basis However, the examinee is given no chance to enlarge on points that particularly interest him or to discuss controversial aspects of the subject Students who have been accepted by recognised medical schools are not being called up, but are offered commissions in the Army or Navy Medical Corps Reserve while they are still in medical school

Ever since arriving in this country I have been impressed by the friendly and generous reception we have had, and very much hope that a reciprocal exchange of American and British medical students may be possible in time to come

* * *

I arrived in one of the younger of the Middle West medical schools last fall after a long and eventful journey From the moment I arrived I was made to feel at home, a few hours after stepping off the train I was enrolled as a member of the third-year class, and next day I was at work For the arrangements made for my reception here, and for the cordiality with which I have been treated I have many to thank, particularly the dean of the medical school, who has in all respects "gone the second mile" with me There is a notable bias in this part of the country towards application of the basic sciences in the practice of medicine There is active cooperation between the clinical groups in the hospital and the departments, particularly of physiology and pharmacology, in the medical school A third-year student has plenty of didactic teaching—even to six urs of lectures in one day The junior student is ven less responsibility than his counterpart in Britain , is taking as it were. a laboratory course—in this case ward work—rather than getting experience in a actical art It is not until his fourth year that he as full opportunities to gain clinical experience By at time he is perhaps better fitted to benefit from them, wever than I was in my earlier ventures into the ards in England. A happy circumstance is the bsence of formality A healthy democratic principle llows a junior student to approach one of the chiefs nd discuss or even criticise his precepts with the utmost eedom The practice is open to abuse but one must ppreciate the coöperation and open-mindedness which is revolution from tradition has brought about in he profession at large.

My school differs from any medical school in Britain nd from many in America in being under state adminis-ration. It is part of a state university. and the hospital s a free hospital subsidised by the state and county uthorities The hospital staff is employed on a more or ess full-time basis by the university or by the department f health of the state This is in contrast to organisa-ion in England, but from the students' standpoint the difference from a teaching hospital in England was less than I expected and perhaps hoped

The last two years in medical school are being generally pruned Though any shortening of the medical course must be regarded with concern in this school an intelligent compromise is being made between the ideal and the lengthy training of peace-time and the shortened war-time programme of medical training now being considered throughout the country. Even in the two years I am to be at this school my course will be shortened by ten weeks, by elimination of vacations and curtailment of courses The year of interneship an integral part of the medical course, is fully protected from interference, but after that the qualified doctor who has been enrolled since the age of 21 on the Army or Navy Reserve will be called into service immediately Severely curtailed facilities for postgraduate specialisation are being at present reserved for the lame the blind and the female

* * *

There were many enchanting incidents during the voyage for example, there were the Northern Lights for which we had a front row seat the phosphorescent wake behind the ship. and the school of porpoises which lay ahead of us just beneath the surface of the water; those indeed made some of us start looking for our life-jackets—they looked so like a submarine lying in wait

Once docked in Montreal, the Second French city we lost little time in discarding our seaboots and seeing the night lights A “ jitter bugging ’ contest formed the main attraction for some of us but we were only admiring and, I may say, astonished spectators

Next day we got our first taste of New World universities and hospitals at McGill University and the Neurological Institute, and they were certainly wonderful Our party soon broke up and we set off for our widespread destinations After a train journey taking well over a day, we had our first view of Ol Man River but were not required to “ford it by means of ice floes ”, we used one of the giant bridges Our welcome was American , after a rapid but complete circular tour of St Louis, the festivities were at once opened by a visit to the local stadium to see a ball-game a wonderful introduction to American life with its frankfurters hamburgers. white-shirt-sleeved men and wisecracking crowd Soon afterwards, work claimed all our attention and we found ourselves taken into the fold The most obvious difference from English medical training lies in the almost complete absence of didactic lectures and their replacement by the so-called clinical lecture This does not replace ward work which still takes up the greater part of one s time Being accustomed to the systematic lecture system, one feels that the clinical lecture fails to cover the whole syllabus but, on the other hand, the lectures are certainly more vital American examinations, too, are different being designed to assess the candidate's knowledge more objectively than British examinations , and there is a greater tendency to grade the student on his work throughout the year rather than on examination results alone American hospitals have an advantage over ours in their relatively sound finances this is manifest in their magnificent buildings and excellent equipment The clinical teaching staff includes many more full-time university teachers and research workers and private practice and teaching do not often go together American public health seems to be especially well organised; one very impressive scheme is the publicity given to the lay public on such diseases as cancer. heart disease mental disease and venereal disease Startling results have followed such campaigns There are two of us here at St Louis and we shall be the first to return to England—probably next December In the meantime we plan to get as much out of this trip as we can so that any novel ideas may be tried out at home

* * *

When I arrived I found that the medical course at McGill had been reduced to a total of four years in the medical school and one year minimum of interning Of the four years in the medical school the first and three-quarters of the second are spent in preclinical work, and during the last few months of the second year the student gets an introduction to clinical medicine and learns his general pathology The system was much like the one at Oxford when I was doing preclinical work there at the beginning of the war The principle underlying the work of the third year is that the student should get a fundamental knowledge of the whole field of clinical medicine and an exhaustive knowledge of pathology Education is by a series of lectures and clinics with some practical work and tuition in the wards Thus in special pathology there are two lectures and four more practical classes every week throughout the year. Through the year, too, we have two clinics or lectures each in medicine surgery and obstetrics and gynæcology. every week Other courses of lectures or clinics run for varying lengths of time during the year on pædiatrics public health forensic medicine ophthalmology radiology, therapeutics and other subjects On top of this undercurrent of lectures the whole year is divided into three basic terms for ward work one for obstetrics and gynæcology one for medicine and one for surgery A student in his third year has little responsibility in the wards although more recently progressive reduction in the staff of the hospitals has somewhat altered this Normally his case-histories are mere duplicates and his physical findings tend to be accepted with reserve, which rather damps his enthusiasm However all case-reports are written up with the same care as in an English hospital and are corrected by the chiefs The ward rounds are very good and differ little from their counterparts in England The term in obstetrics is largely designed as a lecture-demonstration course and we get no practical experience in this subject till the fourth year when each student spends nearly a fortnight living in the maternity hospital The McGill course in pathology requires special mention it is a very fine course indeed, and judging from the comments I have heard from people in high places is considered one of the best in the world In the fourth year the student goes over the whole of the field of medicine again in greater detail filling in gaps with more emphasis on the practical side The third year leaves little to the imagination , by the end of it one is expected to know as much as many people know when they graduate from other medical schools At the end of the fourth year the student is given his degree, and becomes an intern It is during this period that most practical knowledge is acquired and although after a year of interning he is allowed to go out into general practice provided that he passes his state examinations, usually he will take another year or even two

The subject matter taught is like that taught in an English hospital, and many of the textbooks are the same, and of course Meakins s Practice of Medicine and Boyd's ‘ Text-book of Pathology ’ are constant findings throughout the university being both excellent and Canadian A point of considerable difference is the large number of examinations we have here oral during the middle of the year, and written and oral at the end I must admit that they are both stimulating and productive of hard labour

Since America's entry into the war the medical course has become more and more concentrated and I fancy the effort over here to get medical students educated quickly and thoroughly compares favourably with the effort in England Vacations are becoming mere skeletons of their former selves, and although on paper it seems that this is no hardship, since normally we get at least two and a half months off in the summer, it is in reality quite a sacrifice Students over here work much harder while they are at medical school, as you may judge from the curriculum, than their English contemporaries, and some students depend on the summer vacation for time to earn money to enable them to complete their course at McGill Then short vacations are useless to some of the students who come from as far afield as California, Texas, Florida, the New England states, the Middle West, and anywhere in Canada, from Vancouver to Nova Scotia Many have farther to travel to get home than I would to get back to England With us here we have the spirit of Osler, and the McGill tradition of research and service More immediately we are much concerned with getting qualified and into the Services

* * *

It is only recently that I have hazarded my hands from the warmth of my bed to the cold of holding a pen, as I am rudely exposed to the frigid air of the Adirondack Mountains in up-state New York Since November I have been confined to a sanatorium as a minimal case of pulmonary tuberculosis and the memory of being precipitated into New York City has diminished in size and clarity At least I can testify to the willing care the Rockefeller Foundation takes of its students' health I can imagine few more potentially desolating situations than to be discovered a "wretched consumptive" in the first few weeks of one's entry into feverish peace But not so such is the attentiveness of this foundation that the whole rather dismal affair is turned into a holiday-cum-exciting experience of the patient's end of things It seems I am being shown the underside of my job as well, rather like the driver of a car being allowed to inspect the guts of his vehicle from the pit of a garage

My entry into the big city was rather like drinking very strong alcohol—I mean when *I* drink very strong alcohol (which is as rarely as possible) Before the dreaded confusion and swirl descends on one, it seems that a stray steam-hammer, with nothing better to do, has taken a sly crack at one's midriff The "Witch's Cavern" of pantomime fame would be a proper representation of my confused entry into furious and break-neck peace What with shops richly stocked, gasoline galore and food aplenty I could scarcely get my breath The only commodity that seemed to be really short and needed to be keenly pursued was time Lease-lend might arrange the shipment of a little of this to New York from England's relative abundance After eating my food in what might have been the booking-hall of a busy railway station for a few weeks, I found myself lost and considerably over-voiced when entertained for dinner in the church-like (or was it normal ?) home of a fellow medical student In spite of assiduous education at the films the most intelligible lecturer, to my alien ear, was a German refugee On buying a newspaper on Sundays I was presented with 120 pages of print of the dimensions of the *Times*—enough to keep me busy for the whole of the following week had I been able to understand more than 10% of it Perhaps the strangest thing of all, in spite of repeated warnings, was the immense hospitality shown to us by everyone we met, this is a thing I shall never forget

With regard to the medical course at Cornell I dare say little, I was so busy absorbing the many innovations and was there so short a time They certainly kept us busy (that might be construed as a British understatement) and we seemed to have every facility in the world at our disposal However, as I say, before I had got over my initial mental indigestion I was seconded to the mountains

* * *

We embarked on a Tuesday in August The party of twelve students formed the entire passenger list of a modest vessel of 5000 tons Our journey was comparatively uneventful, apart from one dive-bombing attack It took us just over three weeks to make the crossing, but at least ten days of our time was spent waiting here and there for convoys We docked at Montreal Neon lights, innumerable cars and plenty of food—these, I think, must have been my first impressions I set out for the Middle West—staying a few days en route in Chicago, a beautiful city, I was fortunate in staying in a hotel on the shores of Lake Michigan, which helped to counteract the effects of gangster films and the novels of Mr Upton Sinclair I was met at the station by four of my fellow students who escorted me to their fraternity and invited me to stay with them I had little trouble in deciding it was an excellent opportunity and I have not regretted that decision The members of this fraternity are all medical students, it resembles our dormitory system in certain ways, but the whole management of the house is in the hands of its members I was much impressed by the size of my foster university The campus is literally a small town on the east bank of the Mississippi, it is well laid out with modern buildings and boasts a university hospital, an auditorium, a palatial union, a daily newspaper, and its own golf links

The medical course formerly occupied four years, with three years premedical work, but since the outbreak of war this has been shortened to three years in medical school by abolishing vacations Didactic work in the clinical subjects is concentrated into the third year, the fourth year being devoted almost entirely to clerkships This has necessitated the inclusion of a great many subjects in the third-year schedule, and as a third year student I have encountered all of them I have been much impressed by the time given to pædiatrics, neuropsychiatry and radiology, I feel they are subjects we in Britain should do well to study more thoroughly Radiology is perhaps more essential in the American curriculum than in our own, since a surprising number of country practitioners have their own X-ray machines of which they make full use The opportunity for elective study in selected fields is one feature of the medical course from which I have benefited greatly Under this system small groups of students may register for these courses and are thus enabled to follow up any subject in which they are interested The final part of the formal medical education is the interneship which must be completed before the university confers the degree of MD

In general the student's attitude towards medicine is more materialistic in the United States than in Britain, at least on the surface, how deep it goes I do not know This may be a direct consequence of the fact that many of the students in medical school must work their way through college

* * *

The first problem that confuses the English student, already awhirl with coco-cola, air-conditioning and high-balls, is the correlation of American and English educational standards High school, junior college, university "med," "pre-med"—how do they correspond to our own system ? They do correspond, though there is perhaps a rather more thorough background to our preclinical courses the essential difference is that the English medical student—in fact any student, arts or natural science—starts to specialise earlier, reaching the final stages of his training when a year or two younger than his American contemporary To the uninitiated observer, the first clinical year seems to be a crescendo of laboratory work routine blood-count, urinalysis and stool examination on all patients, daily counts on all patients receiving sulphonamides and other non-quantitative work as required Fortunately this impression is as unjust as it is superficial Emphasis is predominantly on the *corroborative* value of all laboratory measure An illuminating comparison of the attitudes of our two countries was pointed out by one professor in America, the small-town doctor is often found to be employing the most recent and even experimental methods of treatment, and to be very much up to date in comparison with the more conservative hospitals War has caused one or two changes in our curriculum instead of working three-quarters of a year, we are now to work through a subtropical summer, training thus being shortened The teaching staff is being reduced by half as men are called into the Forces, and the position of the students seems to be less secure than in England On registering "for the draft" students apply for "inactive service" commissions in one of the forces, when they have finished interneship, they are transferred to active service

Some seventy years ago Edward Livingston Trudeau set out from New York to spend what he thought were his last days in the peace and beauty of the Adirondack mountains. He was suffering from advanced pulmonary tuberculosis. The journey, undertaken in mid-winter, was long and arduous, part being made by horse and cart over rough mountain tracks. Contrary to his expectations, Dr Trudeau did not die but lived to found the modern sanatorium treatment of tuberculosis in the United States of America. One year ago I travelled the same route in the luxury of a pullman car, having had the diagnosis of minimal pulmonary tuberculosis made on me by routine X ray a few weeks previously. I could not help finding it a little ironical that, after having avoided bombs and other impedimenta of war for a year or so, the acid-fast bacillus should lay me by the heels. Robert Louis Stevenson lived in the house across the hill from where I am writing. He was here for some months in 1887 when in search of a cure for his consumption. In the words of a letter to a friend during his stay here: "We have a wooden house on a hill top, overlooking a river and a village about a quarter of a mile away and very wooded hills; the whole scene is very Highland, bar want of heather and the wooden houses." The cottage system is in operation; some twenty cottages of brick and wood, each accommodating four or more patients, are scattered over the side of a hill. Set in their midst are the administrative buildings, X-ray departments and laboratories. Treatment is primarily dietetic-hygienic; collapse therapy is only used where these measures have failed. It has been found here that the complications of surgical interference make its indiscriminate use inadvisable.

To the uninitiated the word "sanatorium" conjures up visions of cold bleak corridors and iron bedsteads in which recline the wasted frames of poor phthisical wretches coughing up the last remnants of their bacilli-ridden lungs. My own experience of sanatoria was a little limited, and when people said "You will have a wonderful time at Trudeau" I smiled weakly and thought that never again would I tell any patient of mine "It's only a little operation and won't hurt at all." On my arrival at Trudeau I found the happiest and healthiest community one could ever wish to see. The ambulant patients have the run of lounges, libraries and a workshop with opportunities for fishing and boating and other outdoor occupations which do not involve strenuous exercise. Friends visiting patients generally remark: "Why, it is just like a country club, and where are the patients?" Staff and patients live in harmony, and many ex-patients come and spend their summer holidays at the sanatorium, putting up with a shakedown when the accommodation gets short. Sleeping outside with the temperature thirty below zero is a novel experience. One has the advantage of an electrically heated blanket, but it is a little disconcerting to find the breath freezing on the sheet around one's mouth. For two or three days the subcutaneous facial capillaries rebel, but compensation soon takes place, and after a time it is difficult to sleep in that accursed invention of civilisation, a centrally-heated bedroom. Dr Edward Baldwin, one of Trudeau's earliest assistants, told us of the origin of rest treatment. When the sanatorium was first opened patients were allowed exercise, and in winter bobsleighing was the sport in which most took part. A bobsleighing party had an accident in which one of the members—later to become superintendent of the sanatorium—sustained a compound fracture of the leg. The improvement in his tuberculosis after the rest thus enforced gave the clinicians food for thought which was well digested. When Dr Baldwin himself came to the Adirondacks at the end of the last century for cure he told Trudeau that he had contracted tuberculosis; when asked how he knew, he said that he had used his microscope; this was in 1892. Trudeau remarks on this in his autobiography: "Truly Koch's teaching was beginning to bring practical results." In the medical library attached to the sanatorium a stethoscope turned in wood according to the design of Laennec, with separate ends for heart and lungs, can be seen alongside an original letter from Koch at the time of the discovery of the acid-fast bacillus. The unique collection of historical literature on tuberculosis was made by the late Dr. Lawrason Brown. The other day I came upon a reprint of an essay on the 'Treatment and Cure of Pulmonary Consumption,' written by George Bodington of Sutton Coldfield, England, in 1840. A review of this book in the *Lancet* of July 11, 1840 (p. 575) contains this passage:

> The measures, then, which Dr Bodington assures us have been "uniformly and completely successful in the treatment of several cases of tuberculosis consumption" are detailed in the following passages. . . . More agreeable and seductive medicaments could not certainly be found in any pharmacopœia,—fresh morning air to make the patient breathe, good wine to bring down the pulse; a good dinner to make him fat, and an opium pill to make him sleep, are all excellent remedies if they would only have the desired effect.

Surely this was just another way of saying dietetic-hygienic regime?

* * *

To talk of "American hospitality" is superfluous—it is world-famous. We were at once accepted by our fellow students, not so much as curiosities from an untamed continent, but as their class-mates in the best American sense of the word. Being rapidly assimilated allowed us to make a smooth transition from one system to the other. We arrived in America with a European outlook and a rugged insular ideology, at times at variance with "Americanism." Gradually, by a gentle abrasive process, this attitude becomes less uncompromising and one is able to view our respective cultures more critically. The American student is three years older than his British brother and the chances are that he will marry in his junior years. Before coming to medical school he has spent four years in college, ostensibly pursuing premedical science; but from what I can gather this is the wild-oats period for most American boys. By the time he reaches medical school he is an honest citizen again, diligently pursuing his allotted tasks. There is a tendency in the clinical years to do away with systematic lectures on clinical subjects and to replace these by case-presentations (with discussion and allotted reading). In the wards even junior students are expected to take part in the house routine. This aspect has recently been accentuated by war-time needs. It has the effect of training the student early and correctly, and so prepares him well for the interneship period which is to come after graduation.

In talking of general medicine in the US I am taking a liberty, for my contact with medical practice has so far been casual. Two features strike the newcomer: the high degree of specialisation, and the antagonism to any federal health scheme on the lines of our NHI. This is reflected in the students' outlook, for even as a junior he usually has in mind some particular specialty. Hospitals here enjoy big financial endowments and have a large drainage area. This at once gives the best of them the opportunity to undertake much research and to acquire modern equipment; it also enables teaching hospitals to retain a salaried staff. In comparison British hospitals, supported by the shaky financial framework of voluntary contribution, seem to labour under almost insurmountable difficulties.

* * *

First impressions may not be the soundest, but they are apt to be the most striking. Foremost among mine (though it be animal to say so) was food; not that I suffered from inanition in England, but no sooner had one taken ship than eggs, meat and butter suddenly became abundant. Of the Atlantic crossing, my impressions are chiefly of wondering how to pass the time till the next meal arrived, and listening to Mozart and Beethoven piano and violin sonatas played by two of our number. Our first real taste of lights at night was at Quebec, which we passed about 4 o'clock in the morning, all having tumbled sleepily out of bed to witness this spectacle. But our next lighted city—Montreal—was devoid of all thrill.

* * *

San Francisco was unlike any other city I have ever visited—a collection of superlatives—with two of the world's largest bridges, hills and skyscrapers, blue sea and sky, and white houses with multicoloured roofs. Taken as a whole, as beautiful a city as is to be seen anywhere. My impressions of clinical training in the university to which I am attached are "learn first, practise later";

by which I do not mean to imply that theory and practice are completely divorced from one another, but rather that there is more of a tendency in that direction here than in English medical schools, where theory and practice in clinical teaching are more apt to go hand in hand The four-year system plus the interne year is, roughly speaking, based on this principle and I should hesitate to compare it unfavourably with the English system, for after all the same results are achieved in the end and there is little doubt that the training here is thorough and effective

* * *

I was away on a brief holiday when a telephone call from London summoned me home, I had 48 hours in which to pack all my clothes for two years stay in Canada and to see to my passport, exit permit and the sundry other difficulties in the way of leaving England in war-time At the last moment we were told of the port of embarkation "Be at XY at 12 30 P M tomorrow The train leaves Z at 8 30 A M" It was then late the night before, so I finished my last minute packing and went very tired to bed After a dreary train journey, my one fellow student and I arrived at the port Perhaps there were more ships there than usual, and there was ours and was *that* going to carry us across the Atlantic? We had to give up our gas masks but were allowed to keep our tin hats On board we made rapidly for the dining saloon The first thing we saw was a bowl of oranges and other fruits It couldn't be true but it was At last we left, and the convoy began to take shape Balloons swayed above the ships and RAF planes patrolled the skies Mine-sweepers went ahead and destroyers sped hither and thither getting this and that ship into line We were at the head of the convoy and one of the vice-commodore vessels The next day we were at sea and more and more vessels joined us As soon as land disappeared the order was "Life-jackets must be carried everywhere" All obeyed, though we felt safe enough with the hum of our planes overhead We had all now recovered from the sudden surfeit of food Books were read and finished Cards were played and we got to know all the other passengers That was not very hard Sometimes our escort seemed very worried This and that vessel would be hustled into line, and messages would be flashed or flagged from ship to ship We learnt what some of these meant, but not until later, and we were glad that some of them had proved false We passed a convoy going to England, and a wonderful sight it was We learnt later that it had arrived intact, for Mr Churchill had seen it too Soon it became rather boring and we had read all the books, but we were not to be bored long Suddenly a gale hit us, our little ship pitched and tossed but stood it well, though some of us soon wished the food a little less rich and plentiful After other little excitements we finally arrived in Canada, but not where we could go ashore Four days later we left the boat Montreal is a fine city to arrive at in war-time, it sparkles with lights and there were BANANAS We sat down and ate a bunch in the hotel where the King and Queen stayed when they were there two years before I arrived in Toronto on the morning of one of their national holidays with very little money (most of it had gone on the boat), not knowing a soul and I think given up for lost by my university I acquired some nickels and telephoned no-one was in Finally, through the hospital, I got hold of someone who had heard of me—the dean of the faculty From then on things went well and for a while at least I had a roof over my head The next day I set out for the medical office and after some time, and by devious routes, I reached it It was not more than 200 yards from my front door but I did not know that when I set out Here I duly filled in the various forms required of me People seemed to be a bit wary of me at first but they soon came and asked me questions about this and that I felt rather surprised at the interest people took in the little details of the happenings in England I soon made friends with the other members of my "clinic"—firm, we would say in England People pulled my leg about my accent, but to me the Canadian accent did not sound at all strange

Work here is more concentrated than in England and there are many more examinations But I have skated, skied and played rugger, soccer, squash, tennis and many other games There are many purely Canadian games and entertainments to learn about and these are great fun One meets some very charming people about our campus I have but one complaint to make and that is that everyone thinks I am a Rockefeller scholar I am not, I am a Rockefeller student and there is all the difference in the world between the two

---

SCOTTISH STUDENTS' VIEWS ON THEIR TRAINING

A REPORT representing the opinion of the four Scottish university medical schools—Aberdeen, Edinburgh, Glasgow and St Andrews—has been drawn up by the medical bureau of the Scottish National Union of Students and submitted to the BMA Medical Planning Commission. Its chief points are summarised below.

PREMEDICAL SECTION

A course in biology should replace the present courses in botany and zoology Inorganic chemistry and elementary physics should be taught at school either as part of a syllabus for the higher leaving certificate or as a special postcertificate course for intending medical students University courses would then be in organic chemistry and in applied physics taught with regard to electrotherapeutics, radiology, optics, &c

PRECLINICAL SECTION

The teaching of anatomy and physiology is reasonably satisfactory but insufficient emphasis is laid on their use, they should be more closely correlated Surface anatomy should be more adequately taught Interpretation of normal radiograms should be taught in the anatomy department A course in embryology could be included with biology, but human embryology should be taught with anatomy In physiology the student studies normal function, with which he later compares abnormal function, occasional clinical demonstrations of cases which can be diagnosed on a knowledge of physiology would help him to make such comparisons The study of normal function should include the study of normal psychology Minutiæ should be discarded in favour of essentials

CLINICAL SECTION

Pathology and materia medica should be taught in close relation to subjects being covered at the same time in systematic lectures Students should have the opportunity to follow up any case in the wards which proves fatal and to study the post-mortem findings and sections Tutorial classes are especially useful in the teaching of psychology

Clinics—The number of students attending a clinic should be limited to fifteen Many more teaching clinics should be made available Some degree of uniformity should be achieved by laying down a scheme of clinical teaching Lecture demonstrations and tutorials should largely supplant lectures, and repetition should be reduced to a minimum Cinema films should be used more freely More use should be made of clinical tutors whose main function is teaching The cases seen in hospital bear too little relation to those met in general practice Scottish students have the advantage of access to outdoor hospital dispensaries, but these could be used more fully, and there should be a scheme whereby the student would experience the conditions of general practice before qualifying

Practical work—It is too easy, at present, for a student to pass through his entire course without performing any of the minor medical, nursing and surgical procedures—even without giving an enema Students should have opportunities of stitching wounds, giving injections and undertaking elementary and important nursing routine measures Students should also obtain full experience in giving anæsthetics, this would be of more benefit to him than the long hours spent in watching operations

Midwifery and gynæcology—Practical experience should begin early and be sustained It should be compulsory for students to deliver abnormal as well as normal midwifery cases

Pædiatrics, Special subjects—Diseases of children, midwifery and fevers form a large part of medical practice, and more time should be spent in the [illegible]dy In ching special subjects the emphasis should be on ctical work

Public health and forensic medicine —General principles her than administrative and academic detail should be ight, additional knowledge is acquired by the doctor ien he graduates Interest can be increased by visits id for example to sewage farms or law courts

Additional courses should be given in such subjects the history of medicine, conduct of general practice, ciological relations of medicine and medical ethics

Student residentships —It would be difficult to arrange system whereby every student could act as a resident for iy appreciable period without sacrificing time needed r private study The experience gained would be luable. but experience of general practice would be en more valuable. Every graduate should be com- lled to spend six months—preferably a year—in spital work before being allowed to practise on his wn

GENERAL CONSIDERATIONS

Psychology —The practitioner should be better quipped to diagnose mental disorder early, but sychotherapy and psychiatry are still the field of the pecialist and should not take their place as yet in the edical curriculum A short series of lectures on normal sychology is desirable during the physiology course, to e followed some time during the clinical years with ectures on general psychopathology

Entry to the faculty —No candidate should be deterred y financial embarrassment from entering the medical chool of his choice. There should be equal opportunity or the sexes, and any discrimination against women on rounds of economy or lack of facilities is undesirable. ix years is the optimum length of the course, with entry t the age of 18½ Vacations at present seem dispro- ortionately long, 8–12 weeks a year should be ample.

THE MEDICAL COURSE IN GERMANY AND ENGLAND

BY ONE WHO HAS DONE BOTH

ANY comparison between methods of medical education on the continent before the Nazis came into power and in this country must take into consideration the educational standard of the student before he enters a university. On the continent he must have spent 4 years in an elementary school followed by 9 years at at a secondary school On completion of his school course he had to pass a final examination in anything from twelve to fifteen subjects with a standard equal to the English higher school certificate This examination was the only entrance to a university, and anyone seeking admission was not ordinarily allowed to fail more than once.

During the university course the student was completely free to choose what lectures he attended and no-one was precluded from attending lectures in other faculties Every half-year (semester) one could travel from one university to another and still be eligible to qualify for an examination at any one of them No terminal or sessional examinations were ever held The only three examinations were purely oral and clinical, and corresponded in placing to the English first and second MB and the final In the preclinical course emphasis was laid on principles rather than details Systematic botany was never mentioned but osmosis, turgescence and heliotropism were discussed There was no practical teaching in botany or zoology, and zoological study was devoted to developmental theories, mendelism and physiology rather than to a detailed consideration of differences between the respiratory systems of dogfish and rabbit In physics a general outline was given, no exact knowledge of apparatus was required, no mathematical calculations ever entered into the subject and no practical work was done; the teaching of chemistry, however, was almost identical with that here. The time saved by reduced instruction in these subjects was given to more intensive tuition in anatomy, physiology, histology, neurology and embryology. Anatomy was taught in the first term, whereas here the student must pass the premedical examination before he begins it Dissection was only carried out in winter time During the first session muscles joints and bones, were studied. during the second blood-vessels, nerves and organs, whereas here all anatomical structures are dissected equally carefully from the outset The dissecting-rooms were crowded in many universities The universities are not divided into separate colleges, and consequently lectures were very crowded, often as many as 300 students attending The lack of a college life with all its implications the absence of hostels and licensed lodgings forced the students into unions corps or clubs which catered for widely different tastes These unions—some of which were given up essentially to beer-drinking and fencing others to scientific or political discussion—helped to fill the whole of the student's spare time, since they held meetings every night in the week. The absence of supervision of the personal life of the student by the university authorities meant that he took a far greater share in ordinary life.

Clinical tuition was quite different from that received in this country Students were not attached to a hospital and held no clerkships or dresserships but were merely supposed to attend lectures These lectures were essentially case-demonstrations at which the people in the front row had an opportunity to examine the patients whereas a few hundred people sitting further back merely heard the lecturer discuss the symptoms and signs of the case In surgery an operation would be performed in a huge theatre which could hold a hundred or more people A few students were called down scrubbed up, and had a chance to hold a retractor. The operator explained each step of the operation to the audience who could see very little of the actual surgery These conditions were of course better in smaller universities where the fewer people had a better chance of seeing operations as well as assisting at them Ward rounds existed but were completely useless if conducted by some famous specialist, since a huge crowd would try to surround the bed and nobody at the back could hear or see anything Attendance at outpatient departments by students was comparatively small since there was usually no demonstration attached to it, but an assistant (like an English casualty surgical officer) dealt with the casualties In midwifery the experience obtained in the labour ward was very small, since the student was only called on to be present for two or three sessions of 48 hours to assist in the deliveries, and was rarely allowed to carry one out by himself

Thus it will be seen that the practical experience obtained during the clinical years was small, while theoretical study was probably wider than that of a student sitting for his final in England The real contact between the medical man and his patient on the continent did not start until after the final examination; the successful student then had to work for at least a year as assistant in some hospital department During this period he was normally supposed to write a thesis on some subject on which he had worked and done some research. If this was satisfactory he would have the degree of Dr med. conferred on him at the termination of his assistantship Most people did some original work to acquire this degree, but many others were satisfied with passing the final examination, and after a year's assistantship went into general practice

This description applies chiefly to one large continental university; smaller ones would differ in varying degree To summarise it may be said that on the practical side, the continental system is much less thorough than the English and keeps the student from the living object of his studies; while the theoretical background, by leaving out all unnecessary details in subsidiary subjects, is more concise and more relevant to the ultimate aim of preparing the student for the final examination and fitting him for the requirements of a general practitioner

---

NUTRITION AND INDUSTRY —Five lectures on nutrition and nutritional diseases, which will be of special interest to industrial medical officers, will be given at the Hospitals Centre, Birmingham during September On Sept 8 and 9 the lecturer will be Dr H E Magee, on Sept 15 and 16 Prof V. P Sydenstricker, and on Sept 22 Dr J H Sheldon All the lectures will be at 4 P M and they are open to members of the medical profession by which I do not mean to imply that theory and practice are completely divorced from one another, but rather that there is more of a tendency in that direction here than in English medical schools, where theory and practice in clinical teaching are more apt to go hand in hand The four-year system plus the interne year is, roughly speaking, based on this principle and I should hesitate to compare it unfavourably with the English system, for after all the same results are achieved in the end and there is little doubt that the training here is thorough and effective

* * *

I was away on a brief holiday when a telephone call from London summoned me home, I had 48 hours in which to pack all my clothes for two years stay in Canada and to see to my passport, exit permit and the sundry other difficulties in the way of leaving England in wartime At the last moment we were told of the port of embarkation "Be at XY at 12 30 P M tomorrow The train leaves Z at 8 30 A M" It was then late the night before, so I finished my last minute packing and went very tired to bed After a dreary train journey, my one fellow student and I arrived at the port Perhaps there were more ships there than usual, and there was ours and was *that* going to carry us across the Atlantic? CLINICAL SECTION

Pathology and materia medica should be taught in close relation to subjects being covered at the same time in systematic lectures Students should have the opportunity to follow up any case in the wards which proves fatal and to study the post-mortem findings and sections Tutorial classes are especially useful in the teaching of psychology

Clinics —The number of students attending a clinic should be limited to fifteen Many more teaching clinics should be made available Some degree of uniformity should be achieved by laying down a scheme of clinical teaching Lecture demonstrations and tutorials should largely supplant lectures, and repetition should be reduced to a minimum Cinema films should be used more freely More use should be made of clinical tutors whose main function is teaching The cases seen in hospital bear too little relation to those met in general practice Scottish students have the advantage of access to outdoor hospital dispensaries, but these could be used more fully, and there should be a scheme whereby the student would experience the conditions of general practice before qualifying

Practical work —It is too easy, at present, for a student to pass through his entire course without performing any of the minor medical, nursing and surgical procedures —even without giving an enema Students should have opportunities of stitching wounds, giving injections and undertaking elementary and important nursing routine measures Students should also obtain full experience in giving anæsthetics, this would be of more benefit to him than the long hours spent in watching operations

Midwifery and gynæcology —Practical experience should begin early and be sustained It should be compulsory for students to deliver abnormal as well as normal midwifery cases

Pædiatrics, Special subjects —Diseases of children, midwifery and fevers form a large part of medical practice, and more time should be spent in their study. In teaching special subjects the emphasis should be on practical work.

Public health and forensic medicine—General principles rather than administrative and academic detail should be taught, additional knowledge is acquired by the doctor when he graduates. Interest can be increased by visits paid for example to sewage farms or law courts.

Additional courses should be given in such subjects as the history of medicine, conduct of general practice, sociological relations of medicine and medical ethics.

Student residentships—It would be difficult to arrange a system whereby every student could act as a resident for any appreciable period without sacrificing time needed for private study. The experience gained would be valuable, but experience of general practice would be even more valuable. Every graduate should be compelled to spend six months—preferably a year—in hospital work before being allowed to practise on his own.

GENERAL CONSIDERATIONS

Psychology—The practitioner should be better equipped to diagnose mental disorder early, but psychotherapy and psychiatry are still the field of the specialist and should not take their place as yet in the medical curriculum. A short series of lectures on normal psychology is desirable during the physiology course, to be followed some time during the clinical years with lectures on general psychopathology.

Entry to the faculty—No candidate should be deterred by financial embarrassment from entering the medical school of his choice. There should be equal opportunity for the sexes, and any discrimination against women on grounds of economy or lack of facilities is undesirable. Six years is the optimum length of the course, with entry at the age of 18½. Vacations at present seem disproportionately long; 8–12 weeks a year should be ample.

THE MEDICAL COURSE IN GERMANY AND ENGLAND

BY ONE WHO HAS DONE BOTH

ANY comparison between methods of medical education on the continent before the Nazis came into power and in this country must take into consideration the educational standard of the student before he enters a university. On the continent he must have spent 4 years in an elementary school followed by 9 years at a secondary school. On completion of his school course he had to pass a final examination in anything from twelve to fifteen subjects with a standard equal to the English higher school certificate. This examination was the only entrance to a university, and anyone seeking admission was not ordinarily allowed to fail more than once.

During the university course the student was completely free to choose what lectures he attended and no-one was precluded from attending lectures in other faculties. Every half-year (semester) one could travel from one university to another and still be eligible to qualify for an examination at any one of them. No terminal or sessional examinations were ever held. The only three examinations were purely oral and clinical, and corresponded in placing to the English first and second MB and the final. In the preclinical course emphasis was laid on principles rather than details. Systematic botany was never mentioned, but osmosis, turgescence and heliotropism were discussed. There was no practical teaching in botany or zoology, and zoological study was devoted to developmental theories, mendelism and physiology rather than to a detailed consideration of differences between the respiratory systems of dogfish and rabbit. In physics a general outline was given, no exact knowledge of apparatus was required, no mathematical calculations ever entered into the subject and no practical work was done; the teaching of chemistry, however, was almost identical with that here. The time saved by reduced instruction in these subjects was given to more intensive tuition in anatomy, physiology, histology, neurology and embryology. Anatomy was taught in the first term, whereas here the student must pass the premedical examination before he begins it. Dissection was only carried out in winter time. During the first session muscles, joints and bones were studied; during the second blood-vessels nerves and organs, whereas here all anatomical structures are dissected equally carefully from the outset. The dissecting-rooms were crowded in many universities. The universities are not divided into separate colleges, and consequently lectures were very crowded, often as many as 300 students attending. The lack of a college life with all its implications the absence of hostels and licensed lodgings forced the students into unions corps or clubs which catered for widely different tastes. These unions—some of which were given up essentially to beer-drinking and fencing, others to scientific or political discussion—helped to fill the whole of the student's spare time, since they held meetings every night in the week. The absence of supervision of the personal life of the student by the university authorities meant that he took a far greater share in ordinary life.

Clinical tuition was quite different from that received in this country. Students were not attached to a hospital and held no clerkships or dresserships but were merely supposed to attend lectures. These lectures were essentially case-demonstrations at which the people in the front row had an opportunity to examine the patients whereas a few hundred people sitting further back merely heard the lecturer discuss the symptoms and signs of the case. In surgery an operation would be performed in a huge theatre which could hold a hundred or more people. A few students were called down scrubbed up, and had a chance to hold a retractor. The operator explained each step of the operation to the audience who could see very little of the actual surgery. These conditions were of course better in smaller universities where the fewer people had a better chance of seeing operations as well as assisting at them. Ward rounds existed but were completely useless if conducted by some famous specialist, since a huge crowd would try to surround the bed and nobody at the back could hear or see anything. Attendance at out-patient departments by students was comparatively small since there was usually no demonstration attached to it, but an assistant (like an English casualty surgical officer) dealt with the casualties. In midwifery the experience obtained in the labour ward was very small, since the student was only called on to be present for two or three sessions of 48 hours to assist in the deliveries, and was rarely allowed to carry one out by himself.

Thus it will be seen that the practical experience obtained during the clinical years was small, while theoretical study was probably wider than that of a student sitting for his final in England. The real contact between the medical man and his patient on the continent did not start until after the final examination; the successful student then had to work for at least a year as assistant in some hospital department. During this period he was normally supposed to write a thesis on some subject on which he had worked and done some research. If this was satisfactory he would have the degree of Dr med conferred on him at the termination of his assistantship. Most people did some original work to acquire this degree, but many others were satisfied with passing the final examination and after a year's assistantship went into general practice.

This description applies chiefly to one large continental university; smaller ones would differ in varying degree. To summarise, it may be said that on the practical side, the continental system is much less thorough than the English and keeps the student from the living object of his studies; while the theoretical background, by leaving out all unnecessary details in subsidiary subjects, is more concise and more relevant to the ultimate aim of preparing the student for the final examination and fitting him for the requirements of a general practitioner.

NUTRITION AND INDUSTRY.—Five lectures on nutrition and nutritional diseases, which will be of special interest to industrial medical officers, will be given at the Hospitals Centre, Birmingham, during September. On Sept. 8 and 9 the lecturer will be Dr H. E. Magee, on Sept. 15 and 16 Prof. V. P. Sydenstricker, and on Sept. 22 Dr J. H. Sheldon. All the lectures will be at 4 P.M. and they are open to members of the medical profession.

POSTGRADUATE STUDY IN LONDON

DURING the year facilities for postgraduate teaching had improved a little with the reconstitution of the bombed hospitals and the return of the population to London Doctors are so scarce, however, that the Priority Committee proposes the suspension, during the war, of "all medical postgraduate courses which require whole-time attendance of medical men and women for a considerable period" The Minister of Health has acceded to this recommendation and has asked deans to bring it into operation The courses planned for the coming year are thus likely to be considerably modified in practice, and the following account outlines what was intended rather than what will be performed The Minister takes the view that any student who could attend a full-time course of instruction, even though he may be unfit or ineligible for military service, should undertake work which would release another practitioner to serve with the Forces

The undergraduate medical schools still provide opportunities of work for higher examinations for their own graduates Most schools and hospitals which take postgraduate students in peace-time fall into one of three groups

(A) Those hospitals which are carrying on much the same teaching facilities as before the war

(B) Those hospitals which, as a result of bomb damage or the need for reserving beds for the EMS, have little or no facilities for inpatient teaching, but which continue to teach in outpatient departments, and still offer resident appointments, in some of these selected students can be taken on as clinical assistants and in most of them hospital practice is available by arrangement with the dean

(C) Those hospitals which have had to suspend postgraduate teaching altogether, but which still appoint resident officers and in some cases clinical assistants

The refresher courses for insurance practitioners organised by the Ministry of Health before the war are still suspended, but equivalent instruction is still provided in London by a programme selected from the activities of the various departments of the British Postgraduate Medical School, and to a large extent by practice at the Prince of Wales's, Hampstead General, and Metropolitan Hospitals

GENERAL HOSPITALS

At the British Postgraduate Medical School (group A), although the number of beds is reduced and the full-time staff depleted by the Services, teaching is continuing on prewar lines The ordinary programmes are being carried on in medicine, surgery, obstetrics and gynæcology, and pathology, and the principle is maintained of continuous teaching by the ordinary British methods of bedside tuition and lectures rather than by specific courses The teaching is of a high standard, suitable both for those who merely wish to improve their knowledge and for candidates for higher examinations Special courses on war medicine, fractures, war surgery of the chest, the nervous system, the extremities and abdomen, and on operative surgery, are held in rotation on alternate weeks These intensive courses last a week, to suit the needs of officers in the Services They are advertised in advance in the medical papers, fees are 1 guinea a week for ordinary students and for special courses, except for the fracture course for which the fee is 5 guineas Officers of the forces and of the EMS can be admitted free It is proposed, if circumstances permit, to start the special course for the London University diploma in clinical pathology in October A limited number of students can be given a fortnight's special tuition in anæsthetics, the fee being 3 guineas

The Prince of Wales's, Hampstead General and Metropolitan Hospitals fall into group B, and the Royal Northern, the National Temperance and Queen Mary's Hospital, Stratford, into group C

SPECIAL COURSES

Public health.—At the Royal Institute of Public Health and Hygiene all work, including the course for the D P H, is being carried on normally The annual congress, however, is not being held The course for the D P H of London University usually held at the London School of Hygiene has been suspended Special weekend courses on factory medical services and industrial diseases, however, are held periodically

Psychological medicine—A D P M course is held annually at the Maudsley Hospital (University of London) in the early months of the year In January and February lectures and practical instruction are given on the anatomy and physiology of the nervous system and on psychology, covering part I of the D P M syllabus From March to May inclusive the lectures with clinical demonstrations cover all aspects of psychiatry and mental deficiency, and clinical instruction in psychiatry and neurology complying with the requirements of the examining bodies is also arranged Lectures and demonstrations are also given on neuropathology Since the war the Maudsley Hospital has been emptied of patients and the clinical staff located at the Mill Hill and Sutton Emergency Hospitals, and the clinical instruction in psychiatry is given at these hospitals and also in the London County Council mental hospitals and institutions for mental deficiency Teaching is given in those developments of psychological medicine which have become prominent during the war, such as the clinical application of psychological testing, appraisal of psychometric data, vocational selection, prognosis in traumatic and other neuroses and short methods of treatment Apart from the D P M course clinical instruction in war neuroses and other aspect of psychiatry is continuous throughout the whole year at Sutton and Mill Hill Emergency Hospitals Information can be obtained *from the Honorary Director of the medical* school, Central Pathological Laboratory, West Park Hospital, Epsom, Surrey

Most of the regular training courses at the Tavistock Clinic are in abeyance, the greater part of the staff being engaged in training, research and administrative work in the Services, and the time of the remainder fully occupied with clinical work Doctors have come for individual training, 5 were in training this year, and applications for such training will be welcomed The need for child psychiatrists is at the moment particularly urgent Others have come for training in mental testing, a course attended by 30 doctors has just ended, and applications for individual training in this subject will be favourably received Medical students who intend specialising in psychiatry may consider taking such a course

The course for the diploma in psychology of the University of London is being held at the London School of Hygiene and Tropical Medicine

Tropical Medicine—A diploma in tropical medicine is required by those seeking medical appointments in the tropics Courses of instruction are given at the University of Edinburgh, the Liverpool School of Tropical Medicine [1] and the London School of Hygiene and Tropical Medicine [2] Courses will be held alternately in London and Liverpool for the present, provided there are sufficient applicants The next course, which should begin in September, is to be held in Liverpool but the date is not yet fixed Intensive courses in tropical medicine and parasitology each lasting a fortnight are being held both at Liverpool and at the London School of Hygiene and Tropical Medicine These are mainly for officers of our own and the Allied Services, but civilians may also attend

Neurology—At the National Hospital, Queen Square (B), hospital practice is available to selected clinical clerks (5 guineas for three months, 7 guineas for six months), and outpatient clinics are held each morning at 11 A M, on Monday to Friday (1 guinea for one month, 2 guineas for three months) The West End Hospital (B) holds special classes—consisting of demonstrations of cases with commentaries—for a month four times a year, before each M R C P examination The Maida Vale Hospital (B) provides hospital practice, and may be continuing D P M teaching if it is needed

Heart and lungs—At the Brompton Hospital (B) limited hospital practice is available, and courses are held in preparation for the M R C P and Conjoint examinations The Royal Chest Hospital (B) provides outpatient practice and special courses on heart diseases in conjunction with the Fellowship of Medicine The London Chest Hospital, Victoria Park (B) has been re-established, after the damage it sustained, and provides facilities for hospital practice in all chest diseases including tuberculosis It has a country branch at Camberley Surrey

---

[1] Details may be obtained from the Laboratory Secretary, Liverpool School of Tropical Medicine Pembroke Place

[2] Details may be obtained from the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, W C 1

Children—The Hospital for Sick Children Great Ormond Street (B) is providing limited postgraduate instruction, special consideration will be given to candidates for the diploma of child health The Queen's (C) and Princess Elizabeth of York (C) Hospitals have suspended postgraduate teaching

Maternity—Queen Charlotte's (A) is still offering facilities at Hammersmith subject to war-time conditions The City of London Hospital (C) has been damaged and teaching is still suspended Hospital practice in the maternity department of the British Postgraduate Medical School is available

Cancer and radiology—At the Royal Cancer Hospital (A) teaching continues as before the war. Special courses are held for the final F R C S, both in surgery and in operative surgery, and postgraduate courses are held qualifying for the diplomas in medical radiology of London University and of the Conjoint Board The Mount Vernon Hospital (B) offers hospital practice in its hospital at Northwood; 50 beds are reserved for cancer cases and this number is likely to be increased Additional cancer cases are received under the EMS scheme

Ophthalmology—The Royal London Ophthalmic Hospital (A) is carrying on as usual at Moorfields The Central London (B) continues as usual, except that no special courses are being held

Ear nose and throat—At the Royal National Hospital (B) hospital practice is available but no special courses are held The Metropolitan Hospital (A) is continuing its teaching and classes on outpatients in London and Watford, but all inpatients are transferred to the EMS base hospital Golden Square Hospital (B) provides hospital practice

Orthopædics—The Royal National Orthopædic Hospital (B) has suspended teaching, but the outpatient department is open to postgraduates

Genito urinary and rectal diseases—The London Lock Hospital (A) continues to provide instruction for postgraduates who wish to obtain the 130 hours' instruction required by the Ministry of Health for a special certificate, and teaching facilities generally continue unaltered Hospital practice is available in the outpatient department of All Saints (B) and St Paul's (B) At St Peter s Hospital (B) practice is available in the outpatient department Special courses are held at Colindale on behalf of the Fellowship of Medicine which makes arrangements if there are a sufficient number of applicants.

Skins—Limited hospital practice is available in the outpatient department at the London School of Dermatology (B) and there is a regular teaching session in outpatients at the British Postgraduate Medical School on Thursdays at 2 P.M.

Infectious Disease in England and Wales

WEEK ENDED AUG 15

Notifications—The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever 1332, whooping-cough, 1125, diphtheria, 665, paratyphoid, 13, typhoid, 15, measles (excluding rubella), 4983, pneumonia (primary or influenzal) 440, puerperal pyrexia, 175, cerebrospinal fever 70; poliomyelitis 15, polio-encephalitis, 3, encephalitis lethargica, 2; dysentery, 51, ophthalmia neonatorum, 76 No case of cholera, plague or typhus fever was notified during the week

Deaths—In 126 great towns there were no deaths from scarlet fever or enteric fever, 4 (0) from measles 4 (1) from whooping-cough 15 (1) from diphtheria, 34 (2) from diarrhœa and enteritis under two years, and 11 (1) from influenza The figures in parentheses are those for London itself

Manchester Newcastle-on Tyne and Birmingham each reported 4 fatal cases of diarrhœa and in the same week there were 12 deaths from that disease in Glasgow

The number of stillbirths notified during the week was 219 (corresponding to a rate of 36 per thousand total births), including 18 in London.

OUR thanks are due to deans of medical schools and university officers, to government and municipal officials, to various groupings of students, and to all others who have helped us to give a lively account of medical education in war-time

Reviews of Books

Life and Teaching of Sir William Macewen

A chapter in the history of surgery A K BOWMAN, M B Glasg, regional medical officer to the Department of Health for Scotland. London· William Hodge Pp 425 21*s*

IT is now eighteen years since Macewen died Dr. Bowman gives him place with Harvey, the Hunters, Pasteur and Lister, and regards his contributions to surgery as made to the whole field of medicine Macewen's boyhood was spent on the island of Bute He became a student of Glasgow University where in after years he was to be regius professor At the outset of his career he was hard put to it to make a living, and he worked for eighteen years at the Royal Infirmary before he migrated to the Western in 1892 They were strenuous years His housemen of the eighties still recall with vivid weariness those long night operations, finishing in the small hours, which never seemed to affect Macewen At nine o clock next morning he would be back possessed by his demon of insatiable energy. There were long Sundays in the wards, too, with no break for luncheon He worked as an individual himself the team rather than the member, but helped nevertheless by his succession of devoted assistants His contributions to surgery were launched into a surgical world which his biographer helps us to visualise When he accepted the chair of surgery the creative phase of his life drew to a close, the surgeon and experimenter gave place to the teacher, and his formidable energy was at the service of his students The last ten years of his life were distinguished by war service and presidency of the British Medical Association If it is not always easy, in this biography, to see the man through his works it must be borne in mind that Macewen—perhaps thanks to his intellectual stature—was difficult to understand Dr Bowman s careful research has covered all his scientific and practical achievements his more personal side remains as elusive as it did in life

Demonstrations of Physical Signs in Clinical Surgery

(8th ed.) HAMILTON BAILEY, FRCS Bristol John Wright and Sons Pp 336 25*s*

THIS book has proved its value to the medical student The work is familiar to most of us · it covers the various regions of the body, detailing and illustrating physical signs and explaining their significance More signs are described in it than could be seen in a year in a surgical ward There has been no great change in the general form of the book To each chapter new facts and illustrations have been added which increase its worth to the surgical novice In spite of the loss of many illustrations through enemy action, Mr Bailey, with the assistance of Miss K C Clark, has reproduced most of the fine illustrations with which we are familiar, and, in spite of the modern cult of austerity, has added some coloured photographs The book impresses on the student the value of using his own senses in the diagnosis of surgical disease

Diseases of Women Ten Teachers

(7th ed.) Editor CLIFFORD WHITE, MD Lond, FRCP, FRCOG London Edward Arnold. Pp 435 18*s*

THE seventh edition of this work is a great improvement on what was always a good reliable textbook for the final conjoint and university degrees The retirement of Dr J D Barris and Mr D W Roy has left two vacant places on the editorial committee which have been filled by Mr John Beattie and Mr Douglas MacLeod There has been some rearrangement of the chapters and a few additions A useful chapter on neurasthenia and neurosis in relation to pelvic disorders, and a short section on birth-control, are commendable adjuncts the need of which students and reviewers in the past have stressed The account of the anatomy and physiology of the pelvic genital organs has been carefully rewritten, the anatomy is clearer and better illustrated than before and the chapter on physiology if a little sketchy is adequate In the eighth edition when it comes, the phases of the endometrial cycle might be correlated with the cyclical changes in the ovary Students who use this type of book find it difficult to grasp a true picture of the endothat in order to obtain the best results a similar method should be employed. There is no doubt that the substitution of some form of desoxycholate agar for MacConkey's medium results in the more frequent isolation of the pathogen and should therefore be used whenever circumstances allow. I always recommend this technique to those Service doctors to whom I lecture before they proceed overseas, and I think this is an important topic which cannot fail to interest all doctors now in tropical countries where they will find bacillary dysentery second only in importance to malaria.

RAF Institute of Pathology and Tropical Medicine. A. C. T. VAUGHAN.

THE TEACHING OF SOCIAL MEDICINE

SIR,—By social medicine is meant the practice of medicine which goes outside technical medicine and takes note of the patient as a social unit and as an individual. That is, social medicine tries to ensure that the patient understands, cooperates, has confidence and receives due attention; it also tries to prevent disease and to see that a cure is not invalidated by home or working conditions. Doctors have not altogether failed in putting these principles into practice in the past, but far more can be done, and especially far more can be *taught*. Everyone probably agrees that medical reform is desirable. But the need and importance of teaching the principles and practice of social medicine in our hospitals has yet to be widely discussed. Concrete education and practice are required. Some of the following suggestions could be put into practice overnight; others imply reform of hospital teaching and the curriculum.

Attendance at public health lectures, tuberculosis dispensary, the various special clinics and district midwifery practice will lay a foundation. But there are specific problems. Is 6 months convalescence from acute nephritis possible for this patient? Is it worth operating on a hernia if the patient lives up 60 stairs with no lift? How is a man "rehabilitated"? Where should a child with tuberculous glands be sent? These require more intimate and practical discussion, which could be achieved in several ways: by discussion at outpatients, the almoner being called in perhaps at the end to discuss patients and answer questions about them; by discussion on ward rounds, the almoner perhaps accompanying the round (or the round might end in her office); by seminars or conferences where patients with important social relations could be interviewed and discussed; by field work while clerking, every student making a special study of his own cases; by home visiting, visits to factory or office, and meetings with the family, employer and private doctor; by attending the almoner's office (not more than one or two at a time) and watching the ordinary practice there; by apprenticeship to general practitioners or dispensaries where the importance of social background can be learnt; by having a teaching staff which constantly provokes, and is capable of answering, questions about these things; by official outings to sanatoria, health centres, mental hospitals, rehabilitation centres, nursing homes, special hospitals and the like. The almoner is the hospital specialist in social medicine and will have to be consulted about planning workable schemes.

Part of the patient's confidence and cooperation depends on the personality of the doctor, but if he has to wait hours for attention, or has been curtly dismissed after a few words at the end of it, or if he cannot have a personal and private word with the doctor, or feels herded about, or is treated as an irresponsible nitwit, or is pummelled by students unexpectedly and against his will, or if he neither understands nor has been asked to cooperate in the treatment, his confidence is not going to be at a maximum; and students taught in surroundings where this can happen are not going to turn into perfect practitioners. That this has some weight is shown by two things. First, the reaction of the fresh student on witnessing such happenings—some surprise, if not dismay and disgust, is always felt; by custom the unpleasantness wears away (for the student), but for the new patient it is always acute. Secondly, the fact that very few of those running a teaching hospital would be willing for their close relations and friends to go in as ordinary patients, simply because it is too rough and unpleasant. The ideal must be to produce a hospital to which the staff would be willing to send their own families. Some reforms are clearly needed: an appointment system to save patients from waiting about in outpatients; more staff with more time and more space to work in, so that fuller attention can be given to patients; clear advertisement that the hospital reserves the right to teach on any patient admitted, or preferably the expressed recognition of a patient's right to refuse to be taught on; a limitation, adhered to in practice, on the number of students examining any patient, particularly if he is very ill or in pain. It is commonly objected that no patient has any right to mind a little discomfort considering what expert treatment he receives. But the doctor is trying to eliminate that discomfort so that his treatment may be still more effective and so that the teaching of the human approach is not negatived in practice. Given such hospital organisation, and a suitable teaching staff, it would follow naturally, without lectures, seminars or the like, that the students of that school would treat a patient as an individual in his own right and not as a bag of physical signs.

The most obvious difficulty about all these proposed reforms is the time they would consume. There is little which is not essential in medical education as it stands; the only way of making room for anything more is by expansion. The two fundamental hindrances to this are financial and psychological. Already the medical student has a heavy monetary burden: there are many reasons why the state should—by one channel or another—relieve him of it, at least in the latter part of his training. Apart from financial worry, there is the impatience and boredom which the senior student feels when he is always learning, never doing anything responsible, and of course the longer the curriculum the worse that boredom will become. It could be mitigated by giving students some responsibility at this stage—by letting them work under a general practitioner, or at a dispensary, or with a research team, or arranging for them to take student house jobs.

MEDICAL STUDENT.

THE ILLITERATE STUDENT

SIR,—Your peripatetic examiner who complains of the jargon written in exam papers by medical students should study a few of the textbooks which they have to read. Can you beat this from Gray?

> The extremities or limbs are four in number: a *superior pair* subservient mainly to prehension; and an *inferior pair*, intended for support and locomotion. Both pairs are constructed after a common type, but certain functional differences are observed between them. In the upper limb mobility is the prime consideration, and stability may be endangered in order that the requisite degree of mobility may be obtained. The reverse is the case in the lower limb, where stability must be assured even at the expense of mobility.

I do not think his complaint is justified. Under the stress and worry of an examination one cannot always be bright and think clearly. Surely it is not essential in a practising physician to be able to explain in words of one syllable how the body works. To know how it works is more important. I suspect the examiner of being a research student—i.e., one in a state of arrested development, unfit to judge someone who is going to be a real doctor.

PERIPATETIC DOCTOR.

SIR,—Two peripatetic correspondents have recently written of the illiteracy of medical students. The second correspondent complains of their "smoke-screen of words." May one dare to guess that behind this correspondent's own smoke-screen of verbosity lurks an examiner in physiology—perhaps even the author of one of the many textbooks crowded with the trite, meaningless and incomprehensible phrases of which he complains? He confesses to a hunch. He must be speaking anatomically and has our sympathy, for this purist could never descend to the argot of the Bowery. It is easy to attack the defenceless medical student. Most of them have been doomed from early years to be trained by those who are, by implication, condemned by your correspondent: only a small proportion have had the advantage of being educated. Would he not achieve greater results if he directed his missionary enthusiasm to fellows of the various colleges who are the authors and editors of the phrases of which he complains?

PERIPATETIC STUDENT.

THE COUNTRY HOSPITAL

SIR,—" Students, like children and monkeys," said one of your peripatetic correspondents who wanted country hospitals—and I suppose we are *Nihil animalis a me alienum puto,* and I once saw an honorary throw a placenta at the wall where it stuck, quivering But the monkey-like irritation caused by his classification has prompted me to point out that there really are student-objections to the country hospital Not big objections, although it is inconvenient to have to do inpatients in the country and outpatients in London But such points as that it is, for some reason, cheaper to look after yourself in London than to be looked after in a hostel out of it, that in the country you never see your non-medical friends whereas in London you do, that to have to rely on the medical school library is to realise its inadequacy It's all quite trivial, and I don't see why the hospital, which is for the patients, should mind either way; but I'm not sure that either students, children or monkeys are always as easily led as your correspondent believes I expect he has a way with him And, incidentally, this matter of the patients' preferences Most hospital patients are in bed, so certainly they must like pleasant wards and a nice interesting view out of the window The country's interesting, if the next hut isn't in the way, but so is the shipping on the Thames, or a crowded street, or a children's playground The idea of a country hospital is to combine healing with holiday, presumably, but surely the average hospital patient's idea of a holiday haunt is sometimes a town and almost never a series of huts surrounding a converted white elephant ?

CAND MED

Notes and News

SCIENTIFIC FILMS

FIGHTING, working and living have today become so technical that every citizen must become a scientist if the war is to be won speedily and efficiently Scientific method is needed in production, on the food front, and on the battlefield, and the film, itself fundamentally scientific in material and method, offers a good way of interpreting science to the ordinary citizen

The first scientific films conference, held at the Institute of Mechanical Engineers on August 16, was called by the Association of Scientific Workers, Mr ARTHUR ELTON, chairman of the London Scientific Film Society, presided Dr L KLATZOW, in the absence of Dr J A Lauwerys, spoke on the place of science films in adult education and the training of technicians He pointed out how advances in science are related to technical inventions bacteriology, for example, could never have developed without the microscope, and the film is a new medium for disseminating knowledge Inspired teachers are few and their audiences are necessarily limited in numbers, but with technical cooperation a teacher can teach a world-wide audience of millions through a film The camera can be used to modulate space, time, speed and size, and can therefore present to the audience aspects of a phenomenon which no human eye could observe directly Although slow motion and microcinematography are now familiar to lay audiences, a totally inadequate use of these processes has been made in medical education Nor has the Ministry of Labour made much use of films in industry The position is very different in the United States and the Soviet Union where many films of technical processes in industry and on Army training are freely employed The Ministry of Information has produced some excellent propaganda films, but could make more use of scientific films Films showing the relation of parts to the whole can greatly increase the interest of workers engaged in mass production by demonstrating how each step leads on to the finished product—of which they may have had no clear idea

Mr PAUL ROTHA said that the public were largely scientifically illiterate As a result of the magical "believe it or not" attitude to science in commercial films the ordinary person's conception of science was of bubbling retorts or rockets to the moon A few films, he said, deal reasonably with the lives of scientists such as Ehrlich or Pasteur, but the only film about a British scientist is the life of Michael Faraday, sponsored by the British Council Scientists need propaganda films to shatter the secrecy surrounding their work, and relate it to people's lives Such films must be directed to those who have power to apply science to our daily needs, to the public so that they may know what benefits science has to offer, to the specialist who needs to know how science affects his work in the public interest, and to the scientist himself so that he may know what his fellow scientists are doing Films must range from dramatic persuasion to accurate recording, according to need and purpose The present trouble is he thinks, that one kind of film is often supposed to do all jobs and thus succeeds in doing none

The relation of films to other forms of education was discussed Wireless is used more freely for education in America than in this country, television is a synthesis of film and radio, and opens up new educational perspectives A useful suggestion was that there should be a mobile film unit to record important scientific work in progress A resolution welcoming the setting up of a national Scientific Film Federation, to act as liaison between the existing or projected associations, and to forward national planning and execution was passed unanimously The conference ended with the showing of Paul Rotha's film on blood transfusion an example of the well-produced and informative " documentary "

MD CANTUAR

IN the Middle Ages the Pope had the right to grant academic degrees independently of the universities, and in England he exercised this right through the Archbishop of Canterbury After the Reformation this privilege of the see of Canterbury was reaffirmed by act of parliament and the archbishop was authorised to continue the custom—at the modest price of £4 a degree —for " causes not being contrary or repugnant to the Holy Scripture and Laws of God " This right has never been abrogated, but the status of Lambeth graduates has always been a little unsettled, and in 1722 it was seriously challenged by the Bishop of Chester who refused to admit a BD of Lambeth to the wardenship of Manchester College The courts upheld the archbishop's graduate, but since then it has usually been considered tactful to confer the degree on people who were already graduates of a university Mr R Coleman and Dr Allen Daley's paper at the RSM section of history of medicine of June 3 has been stimulating further research about these degrees of the mitre and a correspondent who has been browsing among back numbers of the *Gentleman's Magazine*[1] writes to tell us of some early medical recipients R Thoroton, MA, of Christ's College, Cambridge, who in 1646 had obtained a licence from the university to practise physic, was granted an MD Lambeth on Oct 31, 1663 Others who received medical degrees in that year were W Fyffe, MA, of Trinity College, Oxford, E, Freeman of Cambridge and P Dakyn who held an MB from an unspecified university Sir Edmund King became MD Lambeth in 1671, and Peter Dent who practised in Cambridge as an apothecary was granted an MB in 1678 With the passing of the Medical Act in 1858 Lambeth degrees of course ceased to be a qualification to practise and since that date only three have been granted—two in 1861 and one in 1862.[2] The last MD Cantuar, William Sharp, FRS, of Rugby, who also held the qualifications of MRCS and LSA, died in 1896 at the age of 91

DIRECTORY FOR THE DISABLED

THE Central Council for the Care of Cripples has published a booklet[3] which will be welcomed by every citizens' advice bureau, hospital almoner or social worker dealing with the physically handicapped It sets out the statutory services available under the Assistance Board, the Board of Education, and the Ministries of Health, Labour and Pensions, the voluntary services provided by the Central Council itself and other agencies, the care offered to the physically defective child, the disabled Service man or woman, the air-raid casualty the industrial worker, and the disabled civilian The appendix gives the addresses of all the agencies sharing in the care of the disabled throughout Great Britain, the homes for crippled children and adults, the orthopædic hospitals and centres, the fracture departments, the employment exchanges connected with EMS hospitals, the Ministry of Pensions hospitals and limb-fitting centres, and the training centres for the physically disabled All this useful information is pleasantly spaced on the pages and easy to follow The council invites suggestions for additions and alterations in future editions

Medical Casualties

The following casualties have been announced

Wounded —Captain A B Waters, MRCS, RAMC, and Captain L G Hannah MB NZ, RAMC

P of W —WS/Captain H C Allan, MB EDIN, RAMC, Captain F J Fish, MRCS, RAMC, WS/Captain D R MacAulay, MB ABERD, RAMC, T/Major K A Moore, FRCS, RAMC, Major E J Pryn, MRCS, RAMC, T/Major H L Thornton, MRCS, RAMC, A/Surgeon Commander H L Cleave, FRCS, RN, Surgeon Lieut Commander W D Gunn, LMS NOVA SCOTIA, RN, T/Surgeon Lieutenant C A Jackson, MB LOND, RNVR, Surgeon Lieut Commander J A Page, MB DUBL, RN, Surgeon Commander R W H Tincker, MRCS, RNVR, and T/Surgeon Lieutenant R G S Whitfield, MRCS, RNVR

Norman Gamble Fund and Research Prize

Applications for this prize and for grants in aid of research work should be sent to the secretary of the Royal Society of Medicine, 1, Wimpole Street, London, W 1, not later than Sept 30

Register of Speech Therapists

The Board of Registration of Medical Auxiliaries have issued a register of speech therapists Medical practitioners, and hospital and educational authorities may obtain free copies from the secretary of the board, BMA House, Tavistock Square, London, W C 1

SIR HENRY DALE, PRS, who was recently appointed a member of the governing body of the Lister Institute of Preventive Medicine, has been elected by the board as its chairman

Appointments

BRODIE, W H, MB ABERD, DPH temp asst MO for Willesden

DAVIS, W B, MD BELF, DPH director of clinical research laboratory, Victoria Infirmary, Glasgow

HARKER, MARGARET E, MB LOND temp asst MO for Ealing

Births, Marriages and Deaths

BIRTHS

BEACH —On Aug 17, at Leintwardine, Bucknell, Salop, the wife of Surgeon Lieutenant Alan Beach, RNVR—a son

BELL —On Aug 19, at Esher, the wife of Mr Arthur C Bell, FRCS—a son

COOMBS —On Aug 11, at Newcastle on-Tyne, the wife of Captain N C Coombs, RAMC—a daughter

LITTLE —On Aug 18, at Woking, Surrey, the wife of Dr G Mellanby Little—a daughter

McOWAN —On Aug 16, at Wellington, Shropshire, the wife of Surgeon Lieutenant B M McOwan, RNVR—a son

MOIR —On Aug 18, at Oxford, the wife of Prof J Chassar Moir, FRCOG—a daughter

MURPHY—On Aug 15, in London, the wife of Dr F D Murphy—a son

REINOLD —On Aug 19, at Sevenoaks, the wife of Surgeon Lieutenant Duncan Reinold, RNVR—a daughter

SOUTHERN —On Aug 16, at Chester, the wife of Lieutenant Dick Southern, RAMC—a son

STEVENS —On Aug 16, in Cairo, the wife of Major C P Stevens, RAMC—a daughter

STOTT —On Aug 21, the wife of Dr N K Stott, of Chobham—a son

MARRIAGES

LAYBOURNE—PIKE —On Aug 8, in London, Maxwell N Laybourne, MRCS, lieutenant RAMC, to Dorothy Joan Pike

DEATHS

BASDEN —On Aug 20, at Taunton, Harold Stevens Basden, MRCS formerly of Crowborough, Sussex, and of Brooke, Norfolk

BIRCH —On Aug 19, at Chipping Campden, Charles Birch MRCS

BLAKEMAN —On Aug 21, at Wonersh, Charles John Blakeman, MRCS, formerly of Cranleigh, Surrey

BODKIN —On Aug 14, at Ringwood, Hants, Herbert Alfred Bodkin, FRCSE, DO, aged 61

BOWLE-EVANS —On Aug 23, at Cheltenham, Charles Harford Bowle Evans, CMG, CBE, MC, MB CAMB, DPH, major general IMS, retd, aged 74

CAMPBELL SMITH —On Aug 22, at Wimbledon, Peter Colin Campbell Smith, MD DURH aged 80

HARRIS —During August, by enemy action, John Richard Glanfield Harris, MB CAMB, D A

JACKSON —On Aug 19, at Holtye, Cowden, Kent, Frederick Douglas Selmes Jackson, MRCS, formerly of Harley Street, W 1

JAMIESON —On Aug 15, at Falmouth, Robert Jamieson, MD GLASG, aged 76

LUNN —On Aug 19, John Reuben Lunn, OBE, FRCS, of Worthing, aged 87

MACPHERSON —On Aug 14 Sir John Macpherson, CB, MD EDIN, FRCPE of Cleeve, near Bristol

RICHARDSON —On Aug 20, in London, Alfred Henry Richardson, MB CAMB, FRCS, of Danby, Yorkshire

"Psychiatry in General Practice" would have been a better title for the précis of Professor Staehelin's postgraduate lecture in our last issue (p 233) He was speaking from his experience as director of a medical clinic in German-speaking Switzerland

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

CERTIFICATION OF DEATH IN INFANCY

F. J. W. MILLER, M.B. DURH., M.R.C.P., D.C.H.
SENIOR CHILD WELFARE OFFICER AND ASSISTANT PHYSICIAN TO THE BABIES' HOSPITAL, NEWCASTLE ON TYNE

DURING 1939 an investigation into the causes of infant deaths was carried out in Newcastle-on-Tyne (Spence and Miller[1]). The essential feature was a personal inquiry by one of two investigators, possessing a knowledge and experience of modern clinical pædiatrics, into the fatal illness and the circumstances of the death of every infant under the age of twelve months. The primary object was to seek accurate information on which to base a plan for the reduction of infantile mortality in Newcastle, but in addition we became interested in the accuracy of certification of death in infancy and the problems concerned therewith. These problems were not described or discussed in the published report.

PURPOSES AND USES OF DEATH CERTIFICATION

Certification of death is a legal duty imposed on the medical practitioner in regular attendance on a patient. He must, in all cases where he has been in such attendance, give a death certificate unless he has reason to suspect that death is due to causes other than natural, or unless the death is sudden from unknown causes or has been directly or indirectly caused by accident. The certificate must give the cause of death to the best knowledge and belief of the doctor and must be completed on the recognised form. After completion it must be delivered to the registrar who registers the death and gives a burial certificate.

The information contained on the certificate is used in preparing the mortality statistics published by the Registrar-General, and their accuracy depends on the care and correctness with which the information is given and the method of classification in use in the Registrar's office. Full information concerning both these points is given in the Manual of the International List of Causes of Death as adapted for use in England, Wales, Scotland and Northern Ireland (H.M. Stationery Office, 3*s.* 6*d.*), which is "an official statement of the practice in force in the several parts of the United Kingdom with regard to the classification of causes of death" and contains "suggestions to medical practitioners respecting certificates of causes of death." The 1938 edition, based on the fifth decennial revision by the International Commission (Paris 1938), came into operation in England in January, 1940. The introduction of this revision coincided with an important change in the method of classification of causes of death. When only one cause of death is given on a certificate it is accepted as the cause of death, but when two or more causes are given there may be difficulties in selecting one for classification. Before 1940 selection was made according to arbitrary rules; certain causes were preferred before others—e.g., prematurity was preferred to almost any other cause of death in infancy. This method had obvious disadvantages and in 1940 a change was made after a "study of a random sample of 10,000 death certificates showed that instances of obvious misunderstanding of the proper use of the form had become comparatively rare and that there was no longer any need to delay the adoption of a method of selection based on the certifier's opinion as to priority of causes" (Manual, p. 7). Since then, except in certain conditions, the morbid condition which started the train of events resulting in death has been considered the actual cause of death. Thus in most cases the practitioner's statement in Space I of the certificate is accepted as the cause of death. When more than one cause is given in Space I, that which was the starting-point of the condition is preferred as the cause of death—e.g., broncho-pneumonia due to whooping-cough is classified as whooping-cough. Causes given in Space I are always preferred to those in Space II unless they are grouped as ill-defined causes of death—e.g., asthenia, marasmus and inanition.[2] If an ill-defined cause is given in Space I and another cause in Space II the death is classified as the latter—e.g., if the immediate cause of death is given as "marasmus" and in Space II prematurity is given as a cause additional to but not in the direct chain of circumstances leading to death, the death will be classified to prematurity.

In certain conditions the Registrar-General may refer the certificate back to the certifier for additional information. For instance, the deaths of all children of more than three months certified as dying from prematurity are subjected to inquiry, so are deaths certified as pemphigus neonatorum, difficult birth, asphyxia or jaundice of the newborn. Yet, strangely enough, no inquiry is made in deaths due to sepsis neonatorum, precipitate labour, atelectasis neonatorum or icterus neonatorum.

Additional information may be forwarded to the registrar if the certifying practitioner initials the appropriate space on the back of the certificate. In this manner the information is collected and classified for use. After the cause of death has been determined classification is made according to the detailed international list of causes of death given in full in the manual.

CHIEF ERRORS OF CERTIFICATION

During our investigation it was possible to compare the causes of death as given on the death certificates with the opinion we expressed as to the most probable cause of death after a close consideration of all the available evidence. The clinical classification given in our report was not comparable with the grouping arrived at by tabulating the causes of death given by certification and no direct comparison will be attempted. But after a consideration of each death certificate in the light of all the available information and making allowances for mere difference in terminology we estimated that at least a third of the certificates gave an inaccurate or inadequate description of the causes of death. Sometimes the inaccuracy appeared to be due to carelessness in certification but most often it appeared to arise because the practitioner did not know the cause of death yet was compelled to give a death certificate unless he was prepared to inform the coroner. That this difficulty exists is shown by the fact that after a consideration of all the available information there was still a large group of deaths—41 (15%) out of 272—in which we were unable to express an opinion as to the cause of death. In most of these cases certificates had been given. As might have been expected the majority of these deaths (33) occurred at home but some (8) occurred in hospitals under conditions which should have given ample opportunities for elucidation of the causes of death; 13 of these children died under circumstances which required a report to the coroner. In only 2 of the 41 cases had a post-mortem examination been obtained. Two examples will indicate the type of case included.

CASE 38.—Female, 10th child, aged 10½ weeks. Healthy born. Weight at 3 weeks, 8 lb. 10 oz. Progress satisfactory; at 9 weeks weighed 10 lb. 7 oz. The child was found dead in her pram and the mother stated that she had been perfectly well when fed some minutes before. Reported to the coroner; the doctor's deposition stated that death was due to infantile convulsions. No autopsy.

CASE 105.—Male, 2nd child, aged 3 days. Healthy born. Birth weight 8½ lb. Born before the arrival of a doctor but good colour and appeared healthy. For 2 days thrived and sucked well but on the third day when midwife went to bathe him he was found grey and cold; he died shortly afterwards. Certified as congenital heart disease.

We found that we classified fewer infants as dying from prematurity alone—i.e., uncomplicated by infection, intracranial injury or other factors—than were certified as having died from prematurity. As a contrast, however, we considered that many more children died from the effects of birth (grouped by us as birth-deaths)—i.e., children suffering from trauma or infections during birth so that they died afterwards. We found that 38 (14%) of the 272 deaths occurred as a direct result of birth, while according to death certificates only 14 (5%) were grouped as birth-injuries. We also differed from the

[2] These conditions relating to death in infancy are given on p. 66 of the Manual of the International List of Causes of Death, 1938 edition.

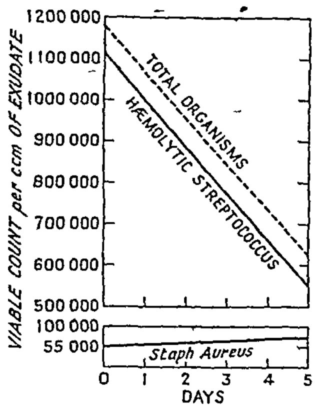

Fig 2—Effect of the application of sulphanilamide on the daily count of viable organisms in an infected abdominal wound

after repeated exposure to it Colebrook (1940) has shown that the more virulent the organisms the more effective are the drugs, but some of the virulent streptococci may possibly persist in a form more resistant but less pathogenic or non-pathogenic The survivors *may be but shadows of* their former selves This is supported by the fact that skin-grafting can be satisfactorily undertaken in spite of the continued survival of some organisms after chemotherapy Tolerance has been investigated by Stamp (1939) who reports the isolation of a factor from the streptococci themselves which is inhibitory to the action of sulphanilamide, and has *shown that the addition of dead organisms to cultures* containing sulphanilamide favours the survival of the organisms under culture and antagonises the sulphanilamide This graph gives no indication of clinical improvement since it fails to record that by the end of three weeks the wound was practically healed, being about a tenth of its original size and healthy *in appearance* in spite of the persistence of some organisms

Fig 2 comes from the case of a girl of 23 who developed sepsis in the abdominal wall after the removal of a gangrenous appendix and shows a similar dramatic fall in the viable count of the predominant organism, the hæmolytic streptococcus, while the small number of staphylococci rose slightly and gradually throughout In the light of further knowledge I feel sure that if the examination had been continued for more than six days the gradual slow rise in the streptococcal count would have appeared Once again clinical improvement was rapid and recovery soon ensued

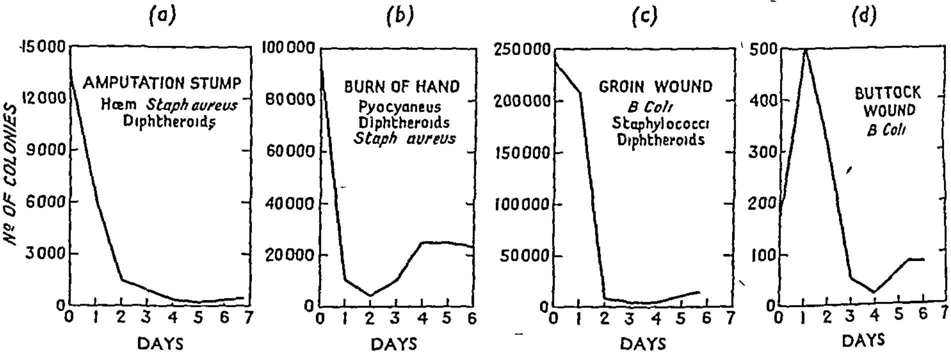

Fig 3—Daily count of viable organisms in chronic wounds after the local application of sulphathiazole powder

Chronic wounds with indolent sloughs and an unreactive appearance are usually infected primarily with the hæmolytic staphylococcus and the *Bacillus pyocyaneus*, and occasionally with the *B coli*, and are accompanied by non-pathogens, the most frequent of which are the diphtheroids, the *Micrococcus catarrhalis* and the non-hæmolytic staphylococci The streptococcus is rarely found on such wounds The bacteriological improvement in these cases was greater than had been expected and I am inclined to regard sulphathiazole as more effective than sulphanilamide in such circumstances, although the series is too small to allow of a dogmatic statement One conclusion however which I have been able to draw is that sulphathiazole is a valuable drug when locally applied to obstinate tuberculous sinuses By this means alone I have seen such a sinus heal in the neck and in the groin where it has resulted from operations, and in the scrotum in a case of tuberculous epididymo-orchitis and on the sternum from an abscess in bone which had been unsuccessfully operated on It is more likely that these results are from destruction of the secondary contaminants of the wound than that they represent bacteriostasis of the tubercle bacilli themselves, but at all events the wounds healed and tuberculosis became clinically completely quiescent

Fig 3*a* comes from an amputation stump in an airman whose finger had to be removed although the hand had also been burnt The operation necessitated the use of a flap which consisted only of scar tissue which sloughed The wound was very slow in healing until sulphathiazole was applied, after which healing was greatly accelerated and the granulations became firm and red The characteristic kick in the graph already discussed is shown and the great fall is gratifying seeing that the predominant organism was the *Staph aureus* and that the wound was extremely chronic

Fig 3*b* is from an extensive burn of the hand to which sulphathiazole was applied It shows the reduction which can be brought about even when one is dealing with the *B pyocyaneus* Research has not offered much *prospect of success when this organism* has been exposed to any of the sulphonamides in vitro, but it is most definitely affected when it is growing on an open wound. Once again the characteristic kick is shown, rising in this instance rather higher than in the majority but nowhere near as high as the original level I was not able to obtain the figures for each organism separately but all three shared in the production of this rise The patient was successfully thiersch-grafted on the seventh day, a layer of the powder being left beneath the graft

The wound from which the counts illustrated in fig 3c were obtained was particularly chronic and sloughs were present in it The bacteriological results were better than was indicated by the appearance of the wound which looked unreactive throughout, but the sloughs came away at the end of the week and the wound was sutured and healed by first intention Maybe the treatment was fortuitous in coinciding with the separation of the sloughs, maybe it assisted it, but it brings out several interesting points First, it did not retard their separation which is a criticism which has been levelled at local chemotherapy, secondly, the action of the drug was unimpaired by the presence of necrotic tissue in spite of the inevitable presence in it of split protein products, and thirdly, it is unlikely that first *intention* healing could have been obtained in similar circumstances without the help of the sulphonamides

Fig 3*d* comes from a wound produced by laying open widely a fistula-in-ano The bacteriological study was begun a week after operation It is a difficult area in which to apply dressings but trouble was taken to exclude the possibility of secondary fæcal contamination The considerable initial rise at the end of the first day's treatment was probably due to the presence of minute quantities of eusol with which the wound had previously been dressed, since this substance, as Francis has pointed out (1941), inhibits the action of the sulphonamides If this is the explanation it is a good demonstration of the harm which can be done by allowing chemicals to come in contact with wounds when sulphonamide therapy is in use Subsequently the graph showed a fall almost to zero on the fourth day followed by a slight but

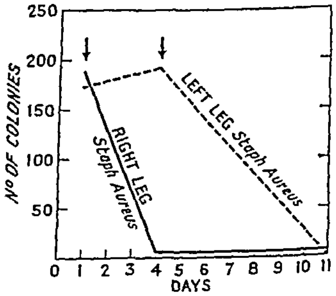

Fig 4—Effect of the application of sulphanilamide powder on the colony count of viable organisms recoverable from symetrical wounds of both legs The arrows denote the first application of the drug to each leg

maintained rise In this case the culture was of pure *B coli*

These results are typical of all the cases I have studied and establish proof that the number of living organisms per unit area of the wound can always be profoundly lowered by the local application of the drugs Sulphanilamide and sulphathiazole were the two drugs used , the choice depended on the type of wound and the nature of the organisms, sulphathiazole being chosen for the more chronic cases and for infections predominantly staphylococcal, sulphanilamide for acute and streptococcal lesions and a mixture of the two in equal parts where this seemed to be indicated A similar fall has not to my knowledge been recorded when the drug has been administered by mouth, and it seems unlikely that the results were merely consequent on the absorption from the raw area into the blood-stream with the production of a systemic action This belief was strengthened by a case of symmetrical scalds of both legs and feet Application of sulphanilamide to one leg left the colony count of the opposite one quite unaltered although a profound fall was seen in the treated limb, while treatment of the opposite side three days later produced in it an equally dramatic fall (fig 4)

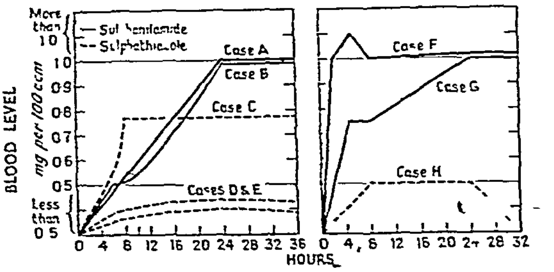

Fig 5—Blood levels Cases A E chronic wounds (4 sq cm approx) Cases F H burns (7 sq cm approx) All exposed to 1 5 g of drug for 36 hours

LEVELS OF SULPHONAMIDE IN BLOOD

In order to obtain further proof that the action was local another series of experiments was undertaken to determine the blood levels following local chemotherapy A measured quantity of the drug was applied to a wound of known extent and left for 36 hours during which time blood was collected at intervals 36 hours was chosen because it was found that the blood level had reached its peak after a single application by this time and because it is not practicable to leave such a wound for longer than this without re-powdering and applying fresh dressing

In all 8 cases were examined by this method 4 using sulphanilamide and 4 using sulphathiazole Fig 5, cases A–E, shows the results in 5 chronic wounds the drugs being estimated by Marshall's colorimetric method Extremely low values are recorded, the highest reaching 1 0 mg per 100 c cm while two of the sulphathiazole administrations produced only traces too small to be recorded by the colorimeter Sulphathiazole produced lower figures than sulphanilamide and appeared to reach its peak rather more quickly All these wounds were approximately 4 sq cm in area The remaining 3 cases, F–H in fig 5 were burns, and the raw surfaces were larger—approximately 7 sq cm in area The peak figures in the burns are much the same 1 0 mg per 100 c cm being only once exceeded and that only in a single sample It is noteworthy that the rate of absorption has been greater, the peak being reached in from two to eight hours instead of twenty-four hours and that once again sulphanilamide gave the higher readings These figures are in agreement with those of Hawking and Piercy (1941) who showed that the peak in 24 cases was reached about twenty-four hours after application and fell rapidly afterwards The low figures are in striking contrast with the level of 3 5 mg per 100 c cm reached in only 2½ hours after the oral administration of the same dose of 1 5 g as recorded by Fuller and James (1940)

It seems probable that to some extent the blood level after local application is proportionate to the extent of the area sprayed and to the amount of the drug used, and high figures with occasional cyanosis have been recorded when large doses have been applied to very extensive areas (Hooker and Lam 1941), one case having severe toxic manifestations and requiring the immediate removal of the powder after receiving the enormous dose of 120 g in two days But it is also probable that absorption is greatly influenced by the type of wound into which the powder is placed Jensen and his colleagues (1939) recorded comparatively high figures after the application of only a small amount of the drug to torn muscles and fractured bones followed by primary suture, but the level dropped quickly after the first twenty-four hours It seems therefore that care should be exercised in the administration of large doses to surfaces whose vascularity will allow of rapid absorption, but it is equally clear from the present experiments that successful bacteriological results are obtained when only a trace or at most 1 mg per 100 c cm has been absorbed into the blood-stream from the 1 5 g locally applied It seems almost certain therefore that the result is due to local action alone and is not dependent on absorption into the blood-stream

LEVELS OF SULPHONAMIDE IN URINE

In these cases the amount of sulphonamide in the urine was estimated over the same period in order to find out what part was played by the kidney It is seen (fig 6) that cases A and B in which sulphanilamide was used showed an excretion representing 12% and 10 7%, while the sulphathiazole yielded 7 4 % 7% and 3 5% These amounts do not of course represent the total excretion since the drugs were obviously excreted for some hours after the dressings had been removed and it is perhaps a pity that samples were not collected until the urine was free, but all show that the peak excretion had been reached at twenty-four hours and passed by thirty-six hours and that the total amounts are considerable The urinary concentrations of course vary with the total amount of urine secreted and are only of interest to show that with the passage of small quantities of a highly concentrated urine they can rise to considerable heights even though the blood concentration is still low Case A shows a concentration of 20 mg per 100 c cm in the urine with a blood level of only 1 mg per 100 c cm in a sample taken at the same time The larger wounds, as would be expected show higher figures the total excretion in 30 hours from the time of application of the drugs being 29 3% in F, 24 6% in G and in H, using sulphathiazole, 19 2% of the 1 5 g applied The urinary concentrations rise as high as 24 mg per 100 c cm and are rarely below 12 mg per 100 c cm

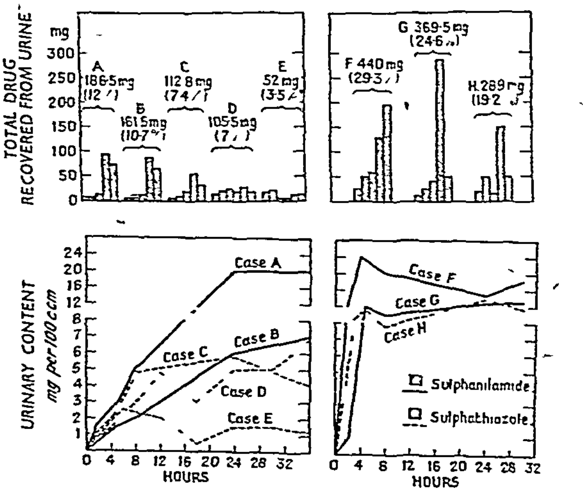

Fig 6—Cases A E and F H as in fig 5 The upper graphs show the amount of the drugs excreted in the urine between the application of the sulphonamide dressing and its removal and the percentage of the 1 5 g applied which these figures represent In cases A C specimens were taken at 2 5 8 24 and 36 hours in cases D and E at 6 12 18 24 30 and 36 hours and in cases F H at 2 5 8 24 and 30 hours The lower graphs show the concentration of the drugs in the urine over the same period

From these observations it is seen that within the first thirty-six hours, in spite of a very low concentration of the drug in the blood-stream, the kidneys are called on to excrete up to 29% of the dose applied and have temporarily to bear high concentrations of the drugs in the urine It therefore seems that care should be taken to exclude renal damage, as evidenced by the appearance of casts, red cells and albumin, in those cases which undergo prolonged local chemotherapy, particularly is this so in treating a large and vascular surface since the amount excreted appears to bear no relationship to the blood level, which is always low I was surprised to find that so much of the drugs had passed through the kidneys and am aware that I have not studied the urine in as much detail as seems to be necessary from these results Generalised toxæmia following local chemotherapy I have never seen

PROPHYLACTIC VALUE

Evidence has been put forward to prove the value of local chemotherapy in the treatment of wounds which are already infected, and in which organisms have invaded the tissues with the production of a greater or lesser amount of slough, and the fact that this action is produced locally has been established Proof of its value in prophylaxis, however, is still wanting and the difficulties here are great There is a very large group of cases in which one is clinically certain that organisms have been introduced but where chemotherapy formed part of the surgical toilet at the original debridement This group includes air-raid injuries, battle casualties, compound fractures and burns, and in order to establish proof of the prophylactic action of the sulphonamides it would be necessary to run a parallel series of similar cases from whom the drugs had been withheld My conviction of their life-saving qualities is so great that I do not feel it is justifiable to withhold them from any such case and I must be content therefore with clinical impressions and observations

There are, however, a few published papers which are useful Jensen and his colleagues (1939) compare the incidence of sepsis in all compound fractures admitted to their hospital during a year before the introduction of the sulphonamides with that occurring afterwards over a similar period The incidence was lowered from 27% to 4 8%, local chemotherapy being the only alteration in treatment King (1941), writing of experiences in the BEF, tells of a ready-made controlled experiment which was forced on him through shortage of the drugs Only the most severely wounded could be given local chemotherapy, yet he had no deaths from this group so long as they were under his care in the casualty clearing station, whereas several of the less severely injured to whom he had been unable to give the drugs died Handley (quoted by Jeffrey 1940) was able to study bacteriologically 25 cases of injury and compound fracture occurring in the Army before the German advance began, and found that 23 of the 25 remained sterile after the local application of sulphanilamide Johnson and Davis (1940) report from America what they describe as " excellent results and primary union " in 273 cases of infected wounds with local chemotherapy

At the London civilian hospital to which I was attached 25 Dunkirk casualties were admitted and about 650 air-raid casualties Of the Dunkirk cases all with open wounds had previously received sulphanilamide, the majority in the form of a locally applied pack, and a few by mouth Most of the wounds were five days old and the lack of sepsis was remarkable, healing was already taking place and surrounding cutaneous infection was minimal or absent These findings are similar to those of the surgeons working in other hospitals to whom I have spoken

Almost all air-raid casualties had multiple wounds, glass cuts being plentiful in the earlier days, and the routine treatment of all clean cut wounds, however caused, was to remove the foreign body, apply the drug and suture the skin This was followed by primary union in the vast majority of cases But administration of sulphanilamide by mouth must follow within 48 hours and be continued for at least four days, since otherwise there is a danger that organisms will recover their virulence after the absorption of the drug before being attacked and destroyed by the leucocytes Experimental evidence on this point has been brought forward by Legroux (1940), who showed that if organisms and sulphanilamide are applied together to a wound which is then sutured sepsis will appear in some of the animals, though it is delayed, while if the wound is reopened and re-sprayed sepsis is prevented It seems reasonable to add sulphathiazole to the sulphanilamide powder in such circumstances owing to its lower solubility and slower absorption The administration of 3 g of sulphanilamide by mouth daily in divided doses for four days was the routine we followed, this appeared to be quite sufficient to supplement the local application and could be discontinued without risk after this time if no sepsis was evident

Those wounds in which there was gross skin loss and maceration of muscle and in which compound fracture was present were subjected to thorough debridement followed by irrigation with hydrogen peroxide through a Higginson's syringe, after which plaster was applied to the limb and the cast cut from end to end and windowed over the wound Powder was then insufflated and the wound covered with dry sterile gauze The irrigation with peroxide and the local application of sulphanilamide were repeated daily through the window and it was striking how quickly the wounds improved Hydrogen peroxide converts sulphanilamide into its oxidation products, which appear to be the active anticatalytic agents, so that this therapy seems logical on chemical grounds and certainly is successful in practice It has already been advocated and tried by Schneider (1941) in America

On ten occasions *B welchii* were isolated from the wounds of air-raid casualties, occurring most commonly in the lower limb but including one case of infection of the brain In one case only—the first—was an amputation performed, and none died I am aware that the presence of anaerobes does not necessarily mean clinical gas gangrene but in these cases local crepitation was present or the muscles were friable, non-vascular and of the characteristic colour It is therefore of some importance to note that all were treated with extensive debridement, daily peroxide soaks followed by sulphanilamide application through their windowed plaster and were in addition injected intramuscularly with anti-welchii serum The rapid improvement in their local and general condition was gratifying Spreading gas gangrene never occurred

Rest of the infected tissues by the application of plaster-of-paris is very important and should be carried out whenever possible, while the end-to-end cut will greatly add to the patient's comfort besides being the only way to guarantee that gangrene cannot occur while supervision is intermittent during transfer to a base hospital Windowing should always be large

Many surgeons have pointed out that it is difficult to obtain an even distribution of powder in wounds and that failures are sometimes due to a part of the wound escaping the direct contact of the drug The ability to penetrate and to spread appears to be very limited and Hawking (1941) has shown experimentally that at a distance of 2 cm no more of the drug is present than is found in the muscles of the opposite limb To overcome this difficulty Schneider (1941) has suggested that a supersaturated solution should be prepared by warming so that on being run into the wound it would be deposited in every nook and cranny as the fluid cooled Sulphanilamide is soluble only to about 0 8% at room temperature but I have determined that at 105° F, which would be safe for local exhibition, this figure is raised to 3 0% in normal saline Schneider actually tried this using heated peroxide but this substance is so unstable that its value is considerably impaired by heating, added to which there seems to be an increased risk of toxæmia following its use To add the warm saline solution after peroxide irrigation would seem more logical

One other word of caution Procaine and its allies contain esters of para-aminobenzoic acid and therefore exert an antagonistic influence on the drugs, so it is necessary to be particularly careful that these are injected round the wound and not into it if their use is essential Cocaine is not antagonistic as it does not belong to this group of drugs Eusol, as Francis (1941) has pointed out, renders the drugs inert so it must be avoided, and it is wise to use dry gauze, or gauze soaked in saline in the case of a dry wound, rather than apply any antiseptics with the drugs

HARMFUL EFFECTS

Research in this country and America has so far brought forward no convincing evidence that the sulphonamides are capable of injuring the leucocytes or the tissues to which they are applied despite one early report by Bricker and Graham (1939) that the tensile strength of fibrous tissue was diminished, this has not been confirmed Russell and Falconer (1940) have studied the rabbit s brain after the application of sulphanilamide and found no irritative or inflammatory changes at the site of application. Glynn (1941) has demonstrated that the organisation of an artifically produced intramuscular hæmatoma takes no longer in its presence, while Key and Burford (1940) have checked radiologically the rate of union of fractures in the rabbit s foreleg in the presence of the drug and found it to be identical with that of controls Bickford (1941) reports that there is no evidence of an inflammatory reaction in the synovial fluid after its exhibition in a joint Colebrook and Francis (1941) found that sulphanilamide certainly had no adverse effect on the healing of superficial wounds infected with hæmolytic streptococci, and it has been my experience that the chances of the "take ' of a tissue so delicate as a Thiersch graft are in no way impaired by the presence of the drug sprayed over the raw area. and in the presence of sepsis are considerably enhanced

SUMMARY

Experimental work in human wounds has demonstrated that the local application of sulphonamides greatly lowers the number of living organisms in an infected wound and that this action is produced locally.

These results are obtained when only a trace, or at most 1 mg per 100 c cm., of the drug is present in the blood-stream, but over the same period the kidney may be called on to excrete a fair percentage of the total quantity exhibited, so that when only a small quantity of urine is passed a high concentration of the drug may be found in it This suggests the advisability of frequent examination of the urine for signs of renal damage particularly when surfaces of more than average vascularity are under prolonged treatment

The great benefits of this form of therapy have been illustrated by reference to macroscopic improvement, to the separation of sloughs and to the results of early grafting and primary suture while its value in the treatment of tuberculous sinuses has been emphasised

In prophylaxis the sulphonamides are of great value, but after primary suture small doses must be given by mouth for four days For wounds in which primary suture is impossible plaster-of-paris is a valuable adjunct but only in so far as it puts the injured part at rest The plaster should be windowed allowing the regular daily application of the sulphonamides after peroxide irrigation. The use of a supersaturated solution obtained by dissolving in saline at 105° F is suggested in order to obtain an even distribution of the drugs in the recesses of the wound. I find no virtue in the practice of encasing an unhealed infected wound in a closed plaster

Chemicals such as eusol should not be used when local chemotherapy is in progress since the majority of such drugs antagonise the sulphonamides as do also the procaine group of local anæsthetics

I wish to thank the Director General of the RAF Medical Services for permission to deliver this lecture, the commanding officer and staff of the RAF hospital to which I am attached, and the staff of the RAF Institute of Pathology, especially Flight-Lieutenant D E Price; and the staff of the Westminster Hospital, especially Dr J G Humble, to whom I am indebted for the bacteriological technique

MAXIMAL RESPONSE TO LIVER THERAPY IN PERNICIOUS ANÆMIA

B L. DELLA VIDA, MD ROME
ASSISTANT PATHOLOGIST ROYAL HOSPITAL WOLVERHAMPTON

Note on dosage by S C DYKE DM OXFD FRCP
DIRECTOR, PATHOLOGICAL DEPARTMENT

WIDE differences exist in the amount of liver extract used in the treatment of pernicious anæmia This arises partly from the employment of extracts of low potency, partly from custom Before steps can be taken to remedy this it is necessary to establish criteria of potency With this in view the data given below were collected from the records of the pathological department of the Royal Hospital It is now established that oral therapy is wasteful and consideration has therefore been confined to preparations for parenteral use The intravenous route was never used

Minot and his colleagues (1928) were the first to introduce a formula from which the potency of liver extracts could be determined; this was derived from the reticulocyte response Their formula was

$$\mathrm{EpR} = \frac{\mathrm{EoR}}{1 - \mathrm{R}} = 0{\cdot}73 - 0{\cdot}2\,\mathrm{Eo}$$

in which Eo is the initial red-cell count Ep the red-cell count at the peak of the reticulocyte rise and R the peak reticulocyte percentage This was subsequently modified by Riddle (1930) to ·

$$\mathrm{R} = \frac{0{\cdot}73 - 0{\cdot}2\,\mathrm{Eo}}{0{\cdot}73 - 0{\cdot}8\,\mathrm{Eo}}$$

Later it was observed that the rise in red cells and hæmoglobin does not in every case follow the rise in reticulocytes and vice versa. The aim of liver therapy is the restoration of a normal red-cell count, the attainment of this and the time in which it is reached must therefore be the values for the assessment of potency of the therapeutic agent This was pointed out by Murphy (1933):

> ' With the introduction of highly concentrated and potent liver extracts for parenteral administration   the magnitude of the reticulocyte response is not directly proportional to the amount of potent material used, nor is the accompanying increase in the erythrocytes necessarily directly proportional *to the rise in reticulocytes* Consequently, and because the primary object of treatment is to elevate the level of and improve the character of the erythrocytes, it would seem advisable to rely more on increases in the erythrocytes, as a means of determining the actual comparative effectiveness of the various substances used '

Recently Riddle (1940), analysing the results obtained in about 600 cases of pernicious anæmia, proposed the formula $\mathrm{I} = 0{\cdot}78 - 0{\cdot}174\,\mathrm{Eo}$ in which I is the average weekly increase in red cells during the first two weeks of treatment, and Eo is the red-cell count before treatment According to Riddle the blood of a satisfactorily treated patient should show a red-cell count of 4 500 000 or more in from 6 to 8 weeks and during the first 2 weeks of treatment an average weekly erythrocyte increase according to the formula Conversely a liver extract of unknown potency tested on a case of pernicious anæmia should be considered fully potent only when the rise in erythrocytes during the first 2 weeks of treatment equals or exceeds that expressed by the formula

MATERIAL STUDIED

During the last 12 years approximately 200 patients suffering from pernicious anæmia have been treated at this hospital, in about 125 of these sufficient data relating to red-cell counts reticulocyte counts and liver extracts employed, were available to enable us to make on to excrete up to 29% of the dose applied and have temporarily to bear high concentrations of the drugs in the urine. It therefore seems that care should be taken to exclude renal damage, as evidenced by the appearance of casts, red cells and albumin, in those cases which undergo prolonged local chemotherapy; particularly is this so in treating a large and vascular surface since the amount excreted appears to bear no relationship to the blood level, which is always low. I was surprised to find that so much of the drugs had passed through the kidneys and am aware that I have not studied the urine in as much detail as seems to be necessary from these results. Generalised toxæmia following local chemotherapy I have never seen.

PROPHYLACTIC VALUE

Evidence has been put forward to prove the value of local chemotherapy in the treatment of wounds which are already infected, and in which organisms have invaded the tissues with the production of a greater or lesser amount of slough, and the fact that this action is produced locally has been established. Proof of its value in prophylaxis, however, is still wanting and the difficulties here are great. There is a very large group of cases in which one is clinically certain that organisms have been introduced but where chemotherapy formed part of the surgical toilet at the original debridement. This group includes air-raid injuries, battle casualties, compound fractures and burns, and in order to establish proof of the prophylactic action of the sulphonamides it would be necessary to run a parallel series of similar cases from whom the drugs had been withheld. My conviction of their life-saving qualities is so great that I do not feel it is justifiable to withhold them from any such case and I must be content therefore with clinical impressions and observations.

There are, however, a few published papers which are useful. Jensen and his colleagues (1939) compare the incidence of sepsis in all compound fractures admitted to their hospital during a year before the introduction of the sulphonamides with that occurring afterwards over a similar period. The incidence was lowered from 27% to 4·8%, local chemotherapy being the only alteration in treatment. King (1941), writing of experiences in the BEF, tells of a ready-made controlled experiment which was forced on him through shortage of the drugs. Only the most severely wounded could be given local chemotherapy, yet he had no deaths from this group so long as they were under his care in the casualty clearing station, whereas several of the less severely injured to whom he had been unable to give the drugs died. Handley (quoted by Jeffrey 1940) was able to study bacteriologically 25 cases of injury and compound fracture occurring in the Army before the German advance began, and found that 23 of the 25 remained sterile after the local application of sulphanilamide. Johnson and Davis (1940) report from America what they describe as "excellent results and primary union" in 273 cases of infected wounds with local chemotherapy.

At the London civilian hospital to which I was attached 25 Dunkirk casualties were admitted and about 650 air-raid casualties. Of the Dunkirk cases all with open wounds had previously received sulphanilamide, the majority in the form of a locally applied pack, and a few by mouth. Most of the wounds were five days old and the lack of sepsis was remarkable; healing was already taking place and surrounding cutaneous infection was minimal or absent. These findings are similar to those of the surgeons working in other hospitals to whom I have spoken.

Almost all air-raid casualties had multiple wounds, glass cuts being plentiful in the earlier days, and the routine treatment of all clean cut wounds, however caused, was to remove the foreign body, apply the drug and suture the skin. This was followed by primary union in the vast majority of cases. But administration of sulphanilamide by mouth must follow within 48 hours and be continued for at least four days, since otherwise there is a danger that organisms will recover their virulence after the absorption of the drug before being attacked and destroyed by the leucocytes. Experimental evidence on this point has been brought forward by Legroux (1940), who showed that if organisms and sulphanilamide are applied together to a wound which is then sutured sepsis will appear in some of the animals, though it is delayed, while if the wound is reopened and re-sprayed sepsis is prevented. It seems reasonable to add sulphathiazole to the sulphanilamide powder in such circumstances owing to its lower solubility and slower absorption. The administration of 3 g. of sulphanilamide by mouth daily in divided doses for four days was the routine we followed; this appeared to be quite sufficient to supplement the local application and could be discontinued without risk after this time if no sepsis was evident.

Those wounds in which there was gross skin loss and maceration of muscle and in which compound fracture was present were subjected to thorough debridement followed by irrigation with hydrogen peroxide through a Higginson's syringe, after which plaster was applied to the limb and the cast cut from end to end and windowed over the wound. Powder was then insufflated and the wound covered with dry sterile gauze. The irrigation with peroxide and the local application of sulphanilamide were repeated daily through the window and it was striking how quickly the wounds improved. Hydrogen peroxide converts sulphanilamide into its oxidation products, which appear to be the active anticatalytic agents, so that this therapy seems logical on chemical grounds and certainly is successful in practice. It has already been advocated and tried by Schneider (1941) in America.

On ten occasions *B. welchii* were isolated from the wounds of air-raid casualties, occurring most commonly in the lower limb but including one case of infection of the brain. In one case only—the first—was an amputation performed, and none died. I am aware that the presence of anaerobes does not necessarily mean clinical gas gangrene but in these cases local crepitation was present or the muscles were friable, non-vascular and of the characteristic colour. It is therefore of some importance to note that all were treated with extensive debridement, daily peroxide soaks followed by sulphanilamide application through their windowed plaster and were in addition injected intramuscularly with anti-welchii serum. The rapid improvement in their local and general condition was gratifying. Spreading gas gangrene never occurred.

Rest of the infected tissues by the application of plaster-of-paris is very important and should be carried out whenever possible, while the end-to-end cut will greatly add to the patient's comfort besides being the only way to guarantee that gangrene cannot occur while supervision is intermittent during transfer to a base hospital. Windowing should always be large.

Many surgeons have pointed out that it is difficult to obtain an even distribution of powder in wounds and that failures are sometimes due to a part of the wound escaping the direct contact of the drug. The ability to penetrate and to spread appears to be very limited and Hawking (1941) has shown experimentally that at a distance of 2 cm. no more of the drug is present than is found in the muscles of the opposite limb. To overcome this difficulty Schneider (1941) has suggested that a supersaturated solution should be prepared by warming so that on being run into the wound it would be deposited in every nook and cranny as the fluid cooled. Sulphanilamide is soluble only to about 0·8% at room temperature but I have determined that at 105° F., which would be safe for local exhibition, this figure is raised to 3·0% in normal saline. Schneider actually tried this using heated peroxide but this substance is so unstable that its value is considerably impaired by heating, added to which there seems to be an increased risk of toxæmia following its use. To add the warm saline solution after peroxide irrigation would seem more logical.

One other word of caution. Procaine and its allies contain esters of para-aminobenzoic acid and therefore exert an antagonistic influence on the drugs, so it is necessary to be particularly careful that these are injected round the wound and not into it if their use is essential. Cocaine is not antagonistic as it does not belong to this group of drugs. Eusol, as Francis (1941) has pointed out, renders the drugs inert so it must be avoided, and it is wise to use dry gauze, or gauze soaked in saline in the case of a dry wound, rather than apply any antiseptics with the drugs.

The average group includes all those cases which responded well to liver treatment, and in which the blood-count was restored to normal in 6–8 weeks The formula $I = 0\ 93 - 0\ 214\ Eo$ corresponds to that found by Riddle for his cases satisfactorily treated with intravenous injections, and is also very near those which can be calculated from the figures given by Isaacs and his colleagues and by Schiødt This formula should be considered as representing a minimal increase of red cells under satisfactory treatment In any case of supposed pernicious anæmia which at the end of 2 weeks fails to show the increase of red cells demanded by the formula the reason must be sought, this will probably turn out to be insufficient dosage due to low potency of the liver preparation, if this or some concomitant deficiency of other hæmopoietic factors (such as thyroxin or vitamin C) is not the cause it will indicate that the patient is suffering from a form of anæmia not amenable to liver

The same formula can be used and is applied at this hospital for the assessment of potency of liver extracts, they are considered fully potent only when the injection of an adequate test dose produces in a patient suffering from pernicious anæmia a red-cell response equal to or higher than that indicated by the formula In about half the cases observed in the pathological department, the red-cell response to a fully potent liver extract has been much higher than that expected from Riddle's formula, and a normal blood-count of 4 500,000 or more has been reached in a shorter time than in most of the cases reported in the literature As stated above the formula obtained in these satisfactory cases is $I = 1\ 30 - 0\ 274\ Eo$

With the exception of those reported by Murphy, no published cases have been found giving a red-cell response as large as that observed in the present series Murphy pointed out the unreliability of the reticulocyte response as a means of assessing the potency of liver extracts, he demonstrated that the increase of red cells may be great when the reticulocyte response is low, and that (as with the reticulocyte response) the increase of red cells is inversely proportional to the initial erythrocyte count He did not as was later done partially by Schiødt, and more accurately and completely by Riddle work out a formula expressing this relationship For comparison with the present series of cases, an equation, given above, has been calculated from the figures given by Murphy, this equation ($I = 1\ 15 - 0\ 235\ Eo$) is in fact closely similar to that obtained from the satisfactory group All other figures and formulæ found in published works, as pointed out above, approximate to the values obtained from the average and in some cases to the unsatisfactory group It is curious that the results obtained in the treatment of pernicious anæmia in this hospital should be better than those previously reported This may be due to the employment only of liver extracts of known high potency

SUMMARY

A series of 125 cases of pernicious anæmia has been reviewed and the relationship between the red-cell count before, and its increase during the first 2 weeks of treatment with parenteral liver extracts has been expressed by mathematical equations

More than half the cases have been found to give a response to treatment better than was to be expected from previously published formulæ

The reticulocyte response does not give an accurate indication of the effectiveness of liver treatment and is therefore not reliable by itself as a means of assessing the potency of liver extracts

The formula $I = 0\ 93 - 0\ 214\ Eo$ (where I is the average weekly increase in red cells during the first 2 weeks of treatment, and Eo is the red-cell count before treatment) has been found to express a satisfactory response to treatment and is proposed as the standard equation for the assessment of the potency of liver extracts

I wish to thank Dr S C Dyke for permission to use the case-records, also Dr A Liebetegger, for assistance in the mathematical analysis

Dosage Dr Dyke

Dr Della Vida points out that only those liver extracts can be regarded as fully potent which, on the injection of an adequate test dose, produce a response satisfying his formula This statement at once raises the question of the size of the adequate dose It is evident that the actual bulk of such an adequate dose will depend upon the concentration of the antianæmic factor in the preparation used Given two preparations the first containing the factor in 5 times the strength of the second the adequate dose of the first will be only ⅕ the bulk of that of the second Unfortunately it is at present impossible to assess the antianæmic factor in "units" An attempt at this has been made by the anti-anæmia preparations advisory board of the United States Pharmacopeia (1938) which has laid down that wording on labels or in package literature must give the information as to the daily dosage necessary to produce a "satisfactory hæmopoietic response" in a case of pernicious anæmia, this daily dose "constitutes a unit" The criterion of a "satisfactory hæmopoietic response" appears to be based on the expected reticulocyte responses calculated from the formula of Minot and his colleagues (1928), and on red cell production A high reticulocyte response is usually the precursor of a satisfactory rise in the red cells, but this Dr Della Vida points out is not always the case It is therefore unsafe to use the reticulocyte response as a criterion of potency in assessing liver extracts The rise of the red cells can alone be regarded as a true indication of potency

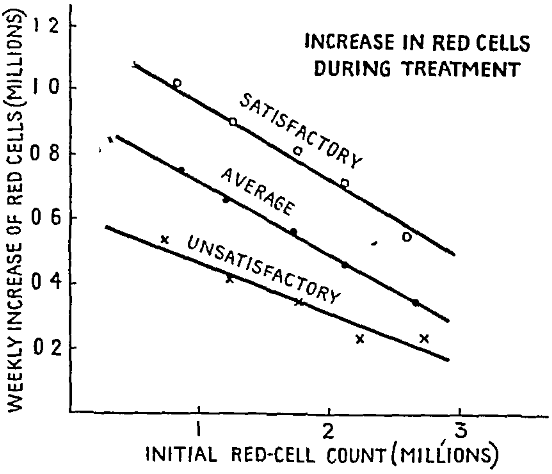
This is not to say that observation of the reticulocytes should be dispensed with, for 3 to 6 days at least from the beginning of treatment the reticulocytes should be counted daily, absence of a response during that period serves as a safe indication that the preparation used is ineffective and that the observation can be discontinued A high reticulocyte response, satisfying the formula of Minot and his colleagues, however, affords no certainty that the red cells will at the end of 2 weeks attain the figures called for by the formula of Riddle (1940), much less that of Della Vida, and in the face of such a response the observation of the red cells must be continued over the full period of 2 weeks

In the cases forming the subject of Dr Della Vida's calculations the actual dosage of liver extract has varied greatly In the early days of the treatment it was the custom to give daily doses, later it was found that with fully potent preparations such frequent dosage was unnecessary In this department a standard dosage of parenteral preparations has been established for the initiation of treatment, this consists of an initial dose of 4 c cm followed at equal intervals during the first week by two doses of 2 c cm and during the second week by a further dose of 2 c cm —a total of 10 c cm during the first 2 weeks This works out as a daily dose over 14 days of 0 715 c cm and each 1 c cm of liver extract would therefore contain at least 1 4 USP units In the absence however of any accurate knowledge as to the actual chemical nature of the antianæmic principle such pretence at accurate assessment appears misleading and likely to cloud the issue It is preferable to dispense with units and to speak of the actual amount of a liver preparation required to produce a red-cell response according to an agreed formula Experience suggests that for this purpose 10 c cm of a fully potent preparation given in the dosage mentioned above over the first 2 weeks of treatment is ample, and it follows that preparations failing to produce the expected red-cell response in this dosage must be regarded as not fully potent and their use as wasteful

We now consider that after the first 2 weeks of treatment a dose of 6 c cm monthly should rapidly bring the red-cell count to normal For maintenance we have found that most cases can be kept in remission on a dose of 4–6 c cm over a period of 2–3 months This may be given divided at monthly intervals or as one injection every 2 or 3 months This is below the dosage employed by many other workers (Wilkinson and Israels 1942) We have found it impossible to establish a depot, no matter how much extract be injected, to last for more than 3 months

I understand from the manufacturers of two of the preparations used in this department that 2 c cm of these represent 20–100 g of raw liver, the same amount of concentrated liver extract prepared by Lederle in USA is stated to be derived from 200 g of fresh liver (Kracke 1937) The use of unnecessarily large quantities of liver extract in the treatment of pernicious anæmia an analytical survey and to compare results with those obtained by other workers

From the data available the average weekly increase in red cells during the first weeks of treatment has been calculated and plotted graphically As Riddle (1940) and other workers point out, the increase of erythrocytes in a satisfactorily treated case of pernicious anæmia is not uniform, but is maximal during the first 2 or 3 weeks of treatment, thereafter becoming less and less the nearer the red-cell count approaches to normal The increase in the first 2 weeks of treatment was therefore selected for the calculation of the weekly increase



At the same time the maximal reticulocyte response of each case was plotted graphically, it was soon noted that, with few exceptions, the cases under review gave a smaller reticulocyte response than that expected from Riddle's (1930) formula Reticulocyte counts vary widely in the hands of different workers and these low responses may be due to differences in technique It was noticed however that a high reticulocyte response did not occur in every case in which the blood count was restored to normal in 4–8 weeks, and which therefore might be considered to be satisfactorily treated It was decided therefore to divide the cases into groups, not following Riddle's criterion of the magnitude of the reticulocyte response but taking into account only the increase in red cells during the first 2 or 3 weeks of treatment

For each patient the erythrocyte count before treatment and the average weekly increase were located on graph paper as one point On plotting all the points these were found to fall into three distinct groups which were empirically labelled "satisfactory," "average," and "unsatisfactory" Next the points in each group were subdivided according to the initial red-cell count at 500,000 intervals (e g, those falling between 500,000 and 1,000,000, between 1,000,000 and 1,500,000, and so on), and arithmetical averages were struck of the figures representing the points within each subdivision, these averages were plotted graphically (see figure) and for each of the three groups an equation was calculated expressing the relationship between initial red-cell count and weekly increment As observed by various workers, the average weekly increase was found to bear an inverse relationship to the initial red-cell count These equations are shown below, with the standard equations suggested by Riddle (1940), and those calculated from the figures of Isaacs and his colleagues (1938) and Murphy (1933)

Average $I = 0.93 - 0.214$ Eo
Satisfactory $I = 1.30 - 0.274$ Eo
Unsatisfactory $I = 0.63 - 0.158$ Eo
Riddle's satisfactory $I = 0.78 - 0.174$ Eo
„ unsatisfactory $I = 0.60 - 0.176$ Eo
Isaacs et al $I = 0.87 - 0.168$ Eo
Murphy $I = 1.15 - 0.235$ Eo

The same procedure was adopted in plotting the averaged reticulocyte responses, the results are shown below It is readily seen that the reticulocyte response of the average group is almost of the same magnitude as that of the satisfactory group, and that the unsatisfactory one gives responses only a few per cent lower than the other two groups Of the three groups of patients the average was found to be the most homogeneous, the standard deviation from the obtained formula being only ± 0.027 million The standard deviation in the unsatisfactory group was ± 0.062 million, and in the satisfactory ± 0.090 million In every group the red cells reached 4,500,000 or more, but the time required to attain a normal count varied from group to group The satisfactory group reached a normal level in 4–6 weeks, the average group in 6–8 and the unsatisfactory group in 8–12 weeks

Red cell count before treatment (millions)	Reticulocytes %		
	Satisfactory	Average	Unsatisfactory
0.90	18.8	17.6	16.7
1.26	18.6	19.3	16.1
1.73	16.4	14.5	9.2
2.33	6.6	1.8	7.4
2.66	7.8		6.2

To show the responses to different extracts and the relationship between initial red-cell count and weekly increment, averages of the points are given for 4 different extracts (see table), these are grouped to show the satisfactory, average and unsatisfactory responses and the range of variation of the weekly red-cell rise

The greatest number of cases falling in the unsatisfactory group were patients treated in the early days of liver treatment, or with test extracts found to be of low potency In a few, although the preparation was of known potency and the dosage adequate, the erythrocyte count did not increase according to the average group formula, the patients nevertheless reached a normal blood-count, but in a longer period of time No particular reason could be found to explain this behaviour The formula $I = 0.63 - 0.158$ Eo given above for these unsatisfactory cases is very similar to that obtained by Riddle for his unsatisfactory cases, and that which can be calculated from the figures given by Schiødt (1939) for cases treated with oral preparations

USE OF ETHYL CHLORIDE SPRAY IN SOFT-TISSUE INJURIES

MAJOR RCAMC

CANADIAN GENERAL HOSPITAL

Within the last few years several observers, including Kraus,[1] Creer,[2] and Cozen and Hollombe,[3] have mentioned the beneficial effects of cutaneous anæsthesia and active movements in acute muscular spasms and sprained joints The results we have obtained with an ethyl-chloride spray in the treatment of lesions of this type have been striking

While rest is indicated in the treatment of bony injuries and infections, it is likely that many, if not all, uncomplicated soft-tissue injuries are far better treated by active movement Not only that, but in injuries of muscles and ligaments rest often leads to embarrassing sequelæ, such as the "frozen" shoulder that may result from rest treatment of trauma to the acromioclavicular ligaments Ethyl chloride sprayed over the tender area of spasm or sprain is a simple anæsthetic agent that will in most cases permit active movement without too much discomfort It is obviously simpler to apply than the injection method but it cannot replace injection treatment in deep-seated lesions such as are encountered in low back pain

TECHNIQUE

This method is not advisable in cases of fracture or torn ligaments or muscles of severe degree To determine if a fracture is present an X ray should be taken The most painful area is then ascertained from the patient and is sprayed with ethyl chloride till the skin is white A full range of passive movement is then carried out when the patient quickly appreciates that the pain on movement is less Occasionally it is found that one or more adjacent areas are painful on movement that were not originally recognised These areas are sprayed in the same way until a complete range of active movement in the affected area is possible without pain Too much anæsthetic must not be used, or frostbite may result Attention must be given to the excess ethyl chloride which may accumulate in a dependent area and produce superficial necrosis of the skin When a full range of movement is attained the area is treated with camphor liniment and massage until a good cutaneous circulation is restored

During the application of the spray a more intense burning and painful sensation is felt than would be felt over a normal surface area treated in the same way This burning sensation vanishes when the spray is stopped A mottled reddish discolorisation may remain for a time afterwards and be associated with mild itching Tenderness over the affected area may persist for some days but as a rule pain on movement is trivial

The patient is told to carry out a full range of movement several times each day though the part should not be subjected to excessive strain In mild cases only one application may be necessary but in more severe ones pain returns range of movement diminishes and a second or third application may be required Since active movement is the basic principle of this method, immobilisation by splint or strapping is definitely not to be employed It is advisable to ask the patient to return on the first and third day after the initial treatment to ensure that the full range of movement is still present and that no untoward complication has arisen

RESULTS

It is early yet to give a complete list of the conditions that might be treated in this manner, but experience so far has shown that acute traumatic lesions of the soft tissues, when not too extensive, give the best results Within this group would be placed sprains such as that of the ankle finger thumb, wrist, elbow, and acromioclavicular joint and minor injuries about the knee If there is delay before these conditions are treated the period of disability will be prolonged Chronic lesions may also be improved but the results are not so striking Late lesions of any of the above conditions, tenosynovitis, pain of indefinite origin and the like have shown remarkable improvement If there is no noticeable response care should be taken that some other underlying condition has not been overlooked

We have already treated 109 patients with the ethyl-chloride spray and active movements They may be subdivided as follows

Sprained ankle	33	Soft-tissue injuries about the elbow	5
Trauma to interphalangeal joints	25	Soft tissue injuries about the wrist	3
Traumatic tenosynovitis	12	Soft-tissue injuries about the knee	4
Direct muscle trauma	10	Contusion of bone	4
Sprain of the acromioclavicular joint	7	Pain of indefinite origin	6

Ankle-joint —By far the largest group have been sprains about the ankle-joint Of these the majority have been about the external malleolus Only 6 cases have had swelling about both the external and internal malleoli Pain on movement, as would be expected is on inversion and plantar flexion The site of tenderness is usually anterior and inferior to the external malleolus Less significance is paid to the localised tenderness than to the sites of localised pain in the treatment The ecchymosis is more noticeable on the day after treatment and tends to be dependent In a few cases the swelling has increased after treatment but as a rule within 24–48 hours the œdema is definitely less and may be entirely gone in 5–6 days The treatment of sprains of the ankle-joint has proved the most satisfactory of all the conditions enumerated

Interphalangeal joints —For the most part the fingers rather than the toes have been treated This group includes a few cases with injuries to the metacarpophalangeal joints as well The areas treated are the lateral, medial and dorsal surfaces of the joint The results have mostly been better than had been anticipated Injuries in these areas are so prone to develop chronic swelling and limitation of movement that some change in the usual methods of treatment seems justifiable It is our impression that there has resulted less fibrosis and periarticular swelling than follow the customary immobilisation

Tenosynovitis —This group includes traumas to the extensor and abductor pollicis longus, tendo achilles, tibialis posticus and the common extensors of the fingers and toes Localised pain and tenderness when contraction of the particular muscle is made against resistance has been the chief sign in the diagnosis, together with a certain amount of swelling in some instances In general these cases have done well

Trauma to muscle —These include contusions of the muscles of the back, thigh and calf with swelling, pain, limitation of function and occasionally ecchymosis The treatment has been beneficial

Sprain of acromioclavicular joint —The acute cases without displacement of the clavicle have done well Those that have a chronic condition the result of a traumatic arthritis, have been improved

Elbow —This group includes not only sprains but also those cases with pain on extension referred to as "tennis-elbow" The sprains have been improved and the tennis-elbows have done extremely well

Wrist —Not many cases of this type have been treated and possibly some have been wrongly diagnosed as tenosynovitis There has been improvement

Knee —Few cases have presented themselves The bulk of traumas in this area result in a torn lateral ligament ruptured meniscus or an effusion into the joint none of which have been treated by this method The few patients treated have been benefited

Contusion of bone —Patients who have had trauma to bone with residual pain have not been improved to any extent by cutaneous anæsthesia

Pain of indefinite origin —This group includes patients with vague pains in the back neck or extremities, in which a definite diagnosis has not been made The treatment has only been given when an X ray has proved negative and local and systemic examinations have failed to reveal underlying disease In 4 instances the patients recovered, the result in the other 2 was indefinite

VITAMIN-C DEFICIENCY IN "IRRESPONSIVE" PERNICIOUS ANÆMIA

S C Dyke B L Della Vida
Elizabeth Delikat M D Bratislava
ASSISTANT PATHOLOGIST, ROYAL HOSPITAL WOLVERHAMPTON

Since the latter part of the winter of the present year we have been faced with the phenomenon of cases of pernicious anæmia proving wholly or relatively irresponsive to liver treatment Various considerations led to the belief that this might be due to a deficiency of vitamin C In certain of these cases the effect of the exhibition of ascorbic acid in full dosage has been such as to confirm this view The following three are illustrative cases

CASE-RECORDS

Case 1 —Female, age 57 First treated at the Royal Hospital in October, 1937 Maintenance established on a dose of 2 c cm of a liver extract of known potency every month In December, 1941, the patient noted that she was not so well, at this time her doctor was unable to procure further supplies of the liver preparation theretofore used and changed to another brand In spite of greatly intensified dosage the patient's condition deteriorated steadily and trial was made of yet another preparation The deterioration in general condition continued When taken into hospital on May 3, 1942, the blood showed Hb 32%, red cells 1,230,000 per c mm, CI 1 3, reticulocytes 2/1,000

Neither of the last two preparations of liver used had been tested in this department and it was thought that the failure to respond might have been due to their relative impotency, the patient was therefore treated with a preparation of known potency in dosage far exceeding that established as "standard" for this department (Della Vida 1942) This dosage produced only a slight and unsatisfactory reticulocyte response Vitamin C in the form of 'Redoxon' (Roche) was then given in doses of 300 mg daily With continuation of the liver dosage the blood condition improved as shown in fig 1 The patient is now well and a blood count four weeks after admission showed Hb 80%, red cells 4,170,000

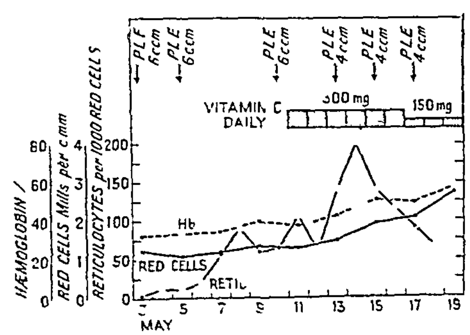

Fig 1—Blood response to parenteral liver extract of known potency (PLE) and vitamin C

Case 2 —Female, age 67 On admission to the Royal Hospital blood showed the typical picture of pernicious anæmia Hb 49%, red cells 1,650,000, CI 1 48, CV 24%, MCV 145 c μ MD 8 5 μ, reticulocytes less than 1/1000, white cells 5400 (polymorphs 62%, lymphocytes 34%, monocytes 2%, eosins 2%) Shift to the right in the Arneth count, anisocytosis, poikilocytosis and basophilic stippling of the red cells Van den Bergh reaction faintly positive indirect Fractional test meal no free HCl

This seemed so definitely a case of pernicious anæmia that it was selected for assaying the potency of a batch of newly prepared liver extract not yet put on the market To this there was no appreciable reticulocyte response and no rise in the red cells In spite of the fact that preparations of liver from this particular firm had always proved highly efficient this aroused suspicion as to the potency of this batch As a test the patient was given the standard dosage of a liver extract of known potency To this also the blood failed to make a satisfactory response The effect of the exhibition of vitamin C in addition to the liver extract is shown in fig 2 A month after discharge from hospital the blood picture shows Hb 73%, red cells 3,840,000, CI 0 95

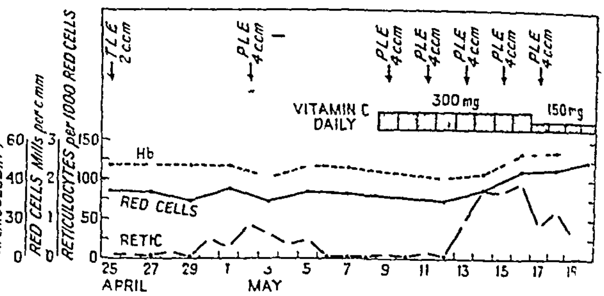

Fig 2—Response in case 2

Case 3 —Male, age 69 First treated at the Royal Hospital in May, 1937 Maintenance dosage established at 4 c cm every eight weeks At the beginning of 1941 the red cell count dropped below 4 000,000 though the patient made no complaint of feeling ill In March, 1942, the red cells were 2 5 millions and the patient's general condition was progressively deteriorating The usual dose of liver extract did not stop the fall of the red cell count On admission to the hospital on May 20, 1942, the blood picture was Hb 36%, red cells 1,190,000, CI 1 51

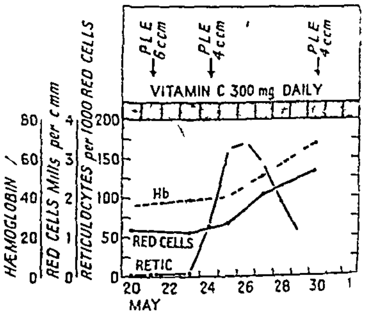

Fig 3—Response in case 3

As shown in fig 3 liver extract of known potency together with vitamin C rapidly restored the blood picture to normal Five weeks after admission the blood count is Hb 82%, red cells 5,280,000, CI 0 78

DISCUSSION

At the time that these patients were under observation —during the spring of the present year—a number of sufferers from pernicious anæmia attending at this department were found in spite of their usual maintenance dosage of liver to be showing a progressive fall in the red-cell count After a month's course of vitamin C 100 mg daily all these patients without any increase in their maintenance dose of liver extract showed a rapid increase of up to 1,000,000 red cells per c mm with corresponding improvement in the general health

A study of the records of pernicious-anæmia patients attending the department reveals the hitherto unnoted fact that during the spring of 1941 and to a lesser extent that of 1940 a proportion of them showed a deterioration in the blood picture, after July the state of the blood tended to improve

That the diet of our general population should be deficient in vitamin C during winter under war conditions was to be expected, that such actually has been the case has been demonstrated by Harris (1942) and Francis and Wormall (1942) The part played by vitamin C in hæmopoiesis is well recognised The above observations serve to demonstrate that in pernicious anæmia, even with ample dosage of the antianæmic principle, hæmopoiesis cannot be returned to normal in the face of a deficiency of vitamin C The implications of this observation both in the treatment of pernicious anæmia and in the testing of liver preparations for therapeutic use are of obvious importance

relieved for many hours each time the two tender spots on the breast were frozen. This helped us to tide her over till she got ease from a moulded support that carried the breast at the relevant time.

* * *

These are only a few examples of relief out of more than a hundred patients treated with ethyl chloride. Many painful conditions were completely cured. Some with low back pain who had not been able to move with comfort did so easily after being frozen. Others were glad of whatever relief they got—an old patient, for instance, with lumbar vertebræ like the sides of guttering candles, whose discomfort was checked by physiotherapy during the time only of its application, had relief with lumbar freezing for seven hours and came repeatedly to get it. Such relief of pain (apart from cure of its cause) by simple harmless means which can be tried again and again is, as a friend used to say, "not nothing."

My colleagues, I know, felt a robust dubiety, till they began to try the thing for themselves. Many too, will picture these patients as objects of nothing more than suggestion enforced by a volatile jinnee from a bottle. And they will be wrong, as my last case proves. Here is a note written by her mistress, Dr. Meave Kenny. Blitz, a small dachshund, aged 7 months, "chased a six-wheel army lorry and was run over by same sustaining severe crushing injury of right paw but no other hurt. Was quite unable to set paw to ground, lay on side moaning and distressed. X rays showed that there was no fracture present; the paw and whole leg, however, were swollen, extremely tender and painful, causing the patient to drool copiously and weep. Four hours after the accident the paw was frozen. Relief was immediate. The patient, who at the start was non-coöperative and belligerent, affectionately saluted the surgeon, leapt off the couch and ran about the room on all paws with only the trace of a limp. About five hours later, the patient not having exercised much in the interval, complete lameness returned and pain again began. Further freezing led once more to complete relief. The slight residual limp and swelling vanished within the next four to five days. The patient will ever pray . . . ."

CASE OF STAPHYLOCOCCAL PNEUMONIA

RECOVERY WITH SULPHATHIAZOLE

JOHN GORDON, M.A. CAMB., M.R.C.S.
FLYING OFFICER R.A.F.V.R.

TRUE staphylococcal pneumonia is relatively uncommon, and with the recent introduction of sulphathiazole as a means of treatment a case that recovered seems worth recording.

At sick parade on the morning of March 31, 1942, an aircraftsman complained of pain behind the eyes, sore throat, cough and pains in the legs; his temperature was 102·6° F., pulse-rate 96 and respirations 24 per min. His throat was red, there were no abnormal physical signs in his chest, and he was admitted to the local isolation hospital as a case of influenza. There the local medical officer of health who examined him found no abnormal physical signs and ordered sulphapyridine 1 g. four-hourly. Thirty-six hours later the patient's temperature had dropped to 98° F., his pulse-rate to 86 and his respirations to 20, but on the third day his temperature again rose to 102·6° F. with a pulse-rate of 90 and respirations 24. His cough was worse, his sputum was tough and rusty, and there was dullness at the base of the right lung with many râles. The sulphapyridine was continued, a purgative was given as he had been constipated, and kaolin plasters applied to his chest. His temperature began to settle again but his cough was still troublesome and he complained of tightness in the chest. On the seventh day he began to get dyspnœa, and the dullness and râles were present at the bases of both lungs. On April 7 his evening temperature was 100·4° F., his pulse-rate 120 and respirations 32; he was given oxygen and brandy. Next morning the temperature had risen to 102° F. with a blood-pressure of 140/50 mm. Hg and as he was cyanosed the sulphapyridine was discontinued and 1 c.cm. nikethamide was given three times a day with the oxygen and brandy. On April 10 his general condition was considerably worse, his blood-pressure was 125/50, and he was coughing up copious blood-stained sputum; the prognosis was exceedingly grave. Next day 5 c.cm. of soluble sulphapyridine was given intramuscularly at noon, followed by 1 g. of sulphapyridine by mouth every four hours. A bacteriological report on the sputum showed *Staphylococcus aureus*, with a few Pfeiffer's bacilli; the blood picture was normal with no leucocytosis. On April 15 the man was even worse: his pulse, temperature, and respirations all began to rise, and as a supply of sulphathiazole was now available he was given 2 g. of the drug every four hours. Two days later he looked much better and his temperature had fallen, but he was still coughing up profuse amounts of sputum and was still cyanosed. Twice daily injections of atropine sulphate gr. 1/200 were given to relieve the congestion. By April 23 he was much improved: his blood-pressure was 112/80, and his white-cell count was 11,000 per c.mm. A throat swab still showed a pure culture of *Staph. aureus*. From this time he had a stormy convalescence, often running night temperatures, but his pulse remained fairly steady and his respiration-rate soon came down to within normal limits. On April 26 the sulphathiazole was discontinued and as it was now possible to move him he was X rayed; this still showed some consolidation at the bases of both lungs. He was given a simple expectorant mixture, and gradually improved until he was discharged from hospital on May 19, after fifty days' treatment.

The geographical position of the area from which I write made the return of bacteriological reports slow, and the sulphathiazole was some time in reaching us; hence the delay in starting sulphathiazole treatment.

Two points seem interesting in this case—first, the complete failure of sulphapyridine in combating the staphylococcal infection, and secondly the depressing effect this drug seemed to have on the leucocyte response. Sulphathiazole seemed to have an opposite effect, producing a well-marked improvement in forty-eight hours, and allowing the leucocytes to respond to the infection at once.

My thanks are due to Dr. R. Stevenson Doig, medical officer of health of this area, for allowing me to publish details of the case.

Reviews of Books

The March of Medicine, 1941

By various authors. New York: Columbia University Press. London: Humphrey Milford, Oxford University Press. Pp. 154. 13s. 6d.

THE sixth series of lectures for the laity, delivered annually at the New York Academy of Medicine and subsequently published under this title, is well up to standard. Of this year's set three might be described as thoughtful, two informative and one historical. Writing one of the first group Dr. Alan Gregg reminds us that science is limited in that it does not give us tastes or values; for these things we must look to humanism to enable us "to counterbalance the exultations and threats of the specialists"; only thus can we become properly educated. Dr. William Healey argues that a knowledge of psychiatry would teach the normal man more about himself and so help him in his social relationships. Dr. Irwin Edman—a doctor of philosophy not of medicine—wants physicians also to be philosophers, but can they help being so? On the purely informative side Dr. Oscar Riddle outlines the potentialities of endocrinology and Dr. Francis Carter Wood does something to dispel the all too widespread notion that we know nothing about cancer. Dr. Henry Sigerist's lecture on Paracelsus paints a sympathetic and understanding picture of that uncouth genius.

The Pleuro-Subpleural Zone

J. SKLADAL, reader in general and experimental pathology, Caroline University, Prague. London: Cambridge University Press. Pp. 103. 10s. 6d.

THE publication of this monograph, delayed by the German occupation of Czechoslovakia, is the outcome of some ten years clinical and experimental research into the properties of the pulmonary expiratory sound and their implications in the diagnosis of various corticopleural lesions of the lung. Dr. Skladal first noted while studying the origin of isolated superficial râles, that if the coughing ordinarily used to elicit them is replaced by a sudden expiration a double expiratory

DISCUSSION

Undoubtedly the most important feature of this method of treatment is the early use of active movement As a result of the initial trauma local pain reflexly sets up muscle spasm to prevent movement and further pain Through some mechanism not readily explainable the ethyl-chloride spray removes the pain which in turn diminishes the amount of muscle spasm and permits the muscle to function again When this has been accomplished, with or without *a second or third application* of the spray, sufficient lymphatic circulation is started to remove the local traumatic œdema On theoretical grounds one would expect an increase in the œdema on the early institution of active movement, and this does occasionally happen, particularly in sprained ankles Its presence, however, is no indication to discontinue the treatment The swelling may increase for 24–36 hours but then quickly disappears so that by the 5th or 6th day little if any œdema remains The speedy and relatively complete diminution of the swelling not only allows a fuller range of movement but prevents the stagnation and chronic induration which leads eventually to periarticular fibrosis and limitation of movement

Naturally the best results are with early and mild traumas, but quite severe lesions with extensive swelling and associated ecchymosis have also been enormously improved immediately and have recovered rapidly It is unwise to treat fractures of bones and tears of major joint ligaments in this manner but fortunately the degree of anæsthesia obtained is not sufficient to permit of this being done

Ready cooperation of the patient is a great help We have found that soldiers may be returned to full duty in a minimum of time while during their period of light duty they have relatively little incapacity

So far by way of complications, there has been little beyond local irritation of the skin There may, of course, be some cases of traumatic arthritis developing later owing to the early use of the part but it is too early for a definite judgment on this possibility

SUMMARY

Local anæsthesia by the ethyl-chloride spray, followed by active movements, has been used in 109 cases of soft-tissue injuries

The method is simple to apply and gives immediate relief and rapid recovery in a large proportion of cases

---

FREEZING WITH ETHYL CHLORIDE
TO RELIEVE PAIN AND LOSS OF MOVEMENT

ARNOLD K HENRY
M B DUBL, M CH (HON) CAIRO, F R C S I
EMERITUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EGYPT

SOME five years ago I heard through a casual visitor from Vienna that the ethyl-chloride spray which we here employ mistrustfully for local anæsthesia there served to encourage patients in moving refractory fingers Just then a waiter for whom we had opened a superficial whitlow returned with his index finger fully healed but so impotent that he was unable to carry a plate It was clear that his case required nothing but encouragement, and I used the ethyl-chloride spray as auxiliary Immediately after the freezing he was able to cross the room carrying a large kidney-dish filled with water between his thumb and the cold finger This quick improvement I put down to the power of suggestion, then I forgot about the method for four years My interest was revived suddenly by my friend, Dr J E O'Loghlen, to whom I and many postgraduate students owe our first acquaintance with a variety of simple, effective expedients for everyday use This time, however, the factor of suggestion seemed to fade into the background, while new factors, just as intangible, came to the fore The following few notes are mere pointers, touching the fringe only of what has developed here in the hands of O'Loghlen

One of the patients who did much to break down my own scepticism was an old lady we knew well I had pinned her fractured neck of femur uneventfully From the first week she had made full movements, but had borne weight on the injured hip only three months later Nine months after operation she began to feel pain in the hip, an X ray showed flattening of the left femoral head She was, we knew, a person of character who did not complain easily, and we failed entirely to relieve her heat, Scott's dressing, 'Veganin' traction did not help at all At a loss, I froze a palm's width of skin in front of the left hip—freezing the skin three times and waiting, as we do, for the red reaction to show between first and second freezings Within two minutes of the third freezing she said "There's a queer feeling going through the joint from front to back," an unusual thing for a "frozen" patient to remark attention being focused more on the surface Asked what kind it was she said "a hot feeling" She also said that her pain had gone We (for there were five witnesses) watched her move her hip, previously held motionless on account of pain, fully in every direction But freezing does not change the shape of femoral heads, and after five days her pain returned That, however, was the first break in her suffering

This patient's remark about the hot feeling led us to look for a temperature change deep down in tissues under an skin area which had been frozen Major Ruscoe Clarke and I made a personal test A hollow needle containing a thermocouple was thrust into the right and left thighs Each needle touched the outer side of the femur at the middle third and was then withdrawn ¼ inch When the mirror-galvanometer reached its zero point the skin in front of one needle was three times widely frozen, and erythema appeared, as is the rule The experiment lasted 80 minutes and during that time the deep temperature did not change in the least

An old naval rating injured his right shoulder and came to me with the diagnosis of probable rupture of the supraspinatus tendon The sensitive points, however, when I saw him, were remote from that site, and maximum pain on pressure was over the tendon of teres major, X ray was negative For six days he had been unable to abduct his right arm from his side After freezing the skin over his shoulder (or rather after making it very cold, for no frost appeared) he was at once able to abduct the arm through 30°, and in a week, with a second freezing, he raised the limb well above his shoulder

One of my younger colleagues hurt his wrist A first X ray disclosed no fracture He could not flex his fingers and his whole wrist was extremely painful A deep hæmatoma showed faintly through the skin in front of the lower end of the radius In the interval before the second X ray—hoping that it too would be negative and that I was dealing with a sprain—I froze a bracelet round the painful wrist Within two minutes he was able to open and close his fist and move the hand and wrist painlessly in every direction Complete relief lasted four hours, then pain and disability returned in full The second X ray showed a crack in the articular surface of the scaphoid Ten minutes after my colleague had gone a woman came with exactly the same painful inability to close her fist, and with an almost identical hæmatoma but with a different fracture—a crack in the distal end of the radius She, like my colleague, could close her hand and move her wrist as soon as the part had been thrice frozen Her relief, unlike his, was lasting though slight pain recurred in five hours

A secretary in a department of pathology, after wrenching her right wrist, found it impossible to do her typing There was a tiny, tender thickening of extensor pollicis brevis beside Dupuytren's snuff-box, and we diagnosed her case as one of stenosing tenosynovitis Later she found writing difficult she was also quite unable to cut cloth with scissors, for stretching out *her thumb* caused distress After freezing she could perform these acts painlessly during the next three or four hours, she even used the scissors to cut thick, folded wads of paper We gave her this relief as often as she cared to come for freezing, and we subsequently cured her by de Quervain's operation, stripping the adherent and locally thickened synovial sheath round the tendons of abductor longus and extensor pollicis brevis

In most of the cases I have treated by freezing—or sometimes by cooling for striking relief can be got short of ice formation—pain or rigidity were in limbs or back But a nurse suffering acutely *during* several months from pain in the left breast, which began before a menstrual period and lasted through its early phase, was completely

THE LANCET

LONDON SATURDAY, SEPTEMBER 5, 1942

HOW AND WHY INFANTS DIE

Despite the cock-a-hooping of the Minister of Health there is an undercurrent of dissatisfaction with our infantile mortality This was manifest in our correspondence columns following a recent study[1] by McNeil of death in the first month and the first year of life Neonatal mortality has here as elsewhere, with the notable exception of Chicago, been unamenable to any direct effort to abate it, and England (and still more Scotland) makes a poor showing against Holland, Sweden, Switzerland and Australasia in the death-rate of the rest of the first year McNeil's thesis is that this excessive rate, now on the increase, is due to serious defects in our nursing and medical control of the baby after birth defects which, he is convinced, can be put right by teaching and training[2] The first requisite is to be sure of the facts, and it is the particular merit of an inquiry by Spence and Miller into a year's infant deaths in a northern city that they were not content with an analysis of the certified causes of death but devised a critical and personal form of investigation *Every such death was reported to them by the local* registrar within 24 hours of its registration and themselves possessing clinical experience of disease in infancy they were able to enlist the willing cooperation of all the certifying practitioners in the city The investigation was preceded by a meeting at which its objectives and methods were discussed and decided But even so there were gaps in the inquiry In only 54 out of the 272 deaths was an autopsy done and then not always by a trained pathologist, and only 19 were in the neonatal period And almost half of these examinations failed to establish the cause of death The more or less definite labels on the registrar's certificates, when revised in the light of informed ignorance, found their way into (1) a group called birth-deaths in which the exact cause of death was not stated, it might have been asphyxia, intracranial hæmorrhage or infection, (2) a group called infection of unknown origin, (3) a group of cases in which no opinion could be given, (4) a group of deaths *apparently* due to prematurity alone These four groups numbered 38, 32, 41, 47, making an aggregate of 158 out of a total of 272 Miller assumes the reader's knowledge of this inquiry in his article on death certification in infancy which appears at the front of the present issue He begins by welcoming the new liberty given in 1940 to the certifier of stating what *started* the baby's illness rather than the incident which carried it off This change of outlook in the Newcastle series would mean many more deaths ascribed to the effects of birth and many more also to gastro enteritis—pointing helpfully to "defects which can be put right" rather than to the prematurity which can only be lived down Seven children dying unhelpfully of "congenital debility" had in a stricter review succumbed to birth injuries (3), infective causes (2), extreme prematurity (1), leaving one unfortunate who had just passed out without giving a clue Asphyxia or atelectasis, on closer examination, all implied some trauma or accident during delivery, often being the sign of intracranial bleeding Miller shows good cause indeed for a revision of classification by a committee of clinical pædiatricians and a special form of certificate to include such additional data as birth-weight, feeding and position of child in family

Although the Newcastle inquiry does not emphasise the importance of the first month, it is then that the problems of prematurity and breast-feeding can be best dealt with, and that the techniques against infection can be learned It is then that the problems common to obstetrics and pædiatrics can be *studied* We badly need some conjoint investigations here obstetrician, pædiatrician, pathologist and physiologist It will require team work of a high order to bring the major problems of prematurity, stillbirth, and neonatal death under searching examination The first month is the beginning of pædiatrics, and very few pædiatricians have any clinical experience of it Midwives are quite inadequately instructed in its pædiatric problems and say goodbye to the baby early in the second week, there is no proper liaison with the health visitor, whose instruction and training in dealing with the baby at this time are very poor The newly qualified doctor has heard little or nothing about the baby in the first month Without study, there can be no teaching, without teaching, nursing and medical practice are bound to be mismanaged Moreover in the new Maternity Services Act there is no specific provision for the expert pædiatric control of the baby in these first dangerous weeks after birth, there is in fact no pædiatrician on the Central Midwives Board A beginning might be made in some of the large centres where pædiatricians intimate with hospital neonatal problems could be used in domiciliary maternity practice It would be as unfair as it would be idle to blame town councils or child welfare services for the present state of infant health, it is a big and difficult problem and the first essential for its control is study Perhaps the chief service of the Newcastle inquiry will have been to show how little we know about these problems Further studies of the kind in all large centres where there are pædiatricians capable of giving them skilled direction should *count as war emergency* The last war initiated the antenatal and the postnatal clinic There is a gap between them still to be bridged

ANÆSTHESIA FOR THE BELLY WOUND

From the anæsthetist's point of view total war has divided the wounded into two classes—those in the cities where facilities for modern anæsthesia are available, and those on the battlefield where apparatus is necessarily minimal To assert that modern methods of anæsthesia have no advantage over the rag-and-bottle is to deny the improved results and safety of the modern major abdominal operation The older surgeons were no less skilled, they too preached and practised careful preoperative treatment, but who would deny the now nearly negligible mortality of an operation such as partial gastrectomy, the very fit patient at the end of the operation and a convalescence in which, as Lahey says, the rôle of the surgeon is but that of the "*innocent* bystander"[2] Seven sound may sometimes be heard This second sound may have two distinct characteristics (1) reduplication (shortly after the sound usually heard in expiration there follows a second sound which may be similar to the first or acoustically more prominent and tubular), (2) triple sound or pulmonary gallop rhythm (three successive sounds—two comprising the reduplication already described and another sound, less intense than the second, following it without interruption) Metrically expressed the reduplication is iambic and the triple sound anapæstic Dr Skladal has studied the physics of these sounds by means of various instruments The double sound was reproduced on gramophone records and analysed by oscillographs made from gramophone discs as well as from direct recordings and by Fleisch's aerotachograph which registers the speed of the air column The expiratory output was studied with the manometric mask of Pech and the volume of the expired air with a spirometer Lastly, a bellows model was constructed to reproduce the expiratory sounds By means of these experiments he was able to confirm his auscultatory observations, and could explore the clinical and radiological signs of corticopleural lesions of the lungs These included visceropleural thickening and lesions of the subpleural areas of the lungs, such as atelectasis, fibrosis and "splenopneumonia" (used to denote a relatively benign form of pneumonia with a sero-albuminous exudate in the alveoli and physical signs resembling those of a pleural effusion) The true corticopleural syndrome, as he describes it in association with his characteristic auscultatory sign, is a thickened pleura with a consolidated cortical parenchyma beneath, whether produced by œdema, sclerosis, congestion or inflammation Radiologically the lesions are characterised by a cortical radio-opacity, likened to "sugar icing on cakes", several examples are reproduced A pseudo-cortical syndrome is also described, caused by simultaneous lesions of the cortical border and the deep portions of the lung Dr Skladal has evidently taken immense pains in collecting his facts and in checking them by laboratory experiment, the result is a closely reasoned and scholarly study

Thoracic Surgery

Charles W Lester, MD, FACS, assistant clinical professor of surgery, New York University London Humphrey Milford, Oxford University Press Pp 141 12*s* 6*d*

For those students of thoracic surgery who like their facts in highly tabulated form this small book will be welcome Each chapter consists solely of classified and numbered sections and subsections with some appended references The few sentences of more than a word or two indicate the views of Professor Lester himself, and the average reader may well regret that these have not been elaborated to the exclusion of some of the baldly stated and less important facts The subject matter is as up to date as could be wished The surgeon with ambitious designs on carcinoma of the lung or œsophagus will find the possible procedures detailed for him The same applies to recently developed operations on the heart for coronary thrombosis or patent ductus arteriosus The book is interleaved with blank sheets which invite notes or illustrations

Voles, Mice, and Lemmings

Problems in Population Dynamics Charles Elton, director of the Bureau of Animal Population, Oxford London Humphrey Milford, Oxford University Press Pp 496 30*s*

The interrelationship between man and the lower animals is apparent in many fields of life The medical aspect of this relationship is important to the profession, but it is as well to be reminded occasionally of the profound influence of the animal kingdom on man's economic and social well-being The first part of Elton's book is historical dealing with vole and mouse plagues throughout the world from the Pentateuch to the present time The earlier plagues make fascinating reading but are less scientifically satisfying than those of more recent date The second part of the book deals with the fluctuations in density of voles and mice in Great Britain and Scandinavia The work of Elton and his colleagues in the Bureau is described Their methods of approach to ecological and epidemiological problems entail the measurement of fluctuations and density of population by means of various census operations, attempts to discover controlling causes in different environments by assessing breeding mortality and movements in their framework of landscape, vegetation, climate and animal associates, an intelligence system for following the vole population cycle in the field a staff of ecologists to organise the collection of material at the crucial time, a stock of laboratory-bred voles for experiments, and pathological investigations Elton also discusses the effect, in northern Canada, of the density of the mouse population on fur-bearing animals and thus on man, mice are the main food of the foxes it seems, and thus density of fur-bearing population follows the density of mouse population, so that man's chief occupation in that part of the world depends ultimately on the number of mice about The field covered in this book is a vast one, since an immense number of questions await elucidation, but here at least is a scholarly attempt to define the problem

Aids to Surgery

(7th ed) Cecil Joll, MS Lond, MD Brist, FRCS, Reginald C Ledlie, MB Lond, FRCS London Baillière, Tindall and Cox Pp 654 10*s*

Attempts to compress the surgical knowledge required for examination purposes must of necessity result in a book which, though containing sufficient information, fails to convey the broad principles of surgical teaching, but for a concise work to read in conjunction with one of the longer textbooks, this little book will supply a demand Brevity and tabulation, especially in the paragraphs on treatment, may sometimes give erroneous impressions, for instance, incision, heat, passive hyperæmia, serum and general measures are prescribed, in that order, for cases of acute cellulitis, and the accepted principle of delaying the knife in this disease is not mentioned Amputation "at the lowest point at which vessels can be felt to pulsate" is recommended for those cases of senile gangrene which require operation, this seems drastic, and if practised will lead to many disarticulations at the hip The incision described for cases of flexor sheath suppuration of the thumb extends too far proximally, and would divide the motor branch of the median nerve On the whole, however, the book is informative and accurate Abdominal surgery is well described and space is given to alternative methods of treatment The section dealing with injuries has been condensed, as the authors state, from Watson-Jones's textbook on fractures, and obsolete methods which still linger in many surgical textbooks have been omitted

Essentials of Electrocardiography

(2nd ed) Richard Ashman, PhD, Edgar Hull London and New York Macmillan Pp 373 21*s*

The authors, who hold the chairs of physiology and medicine respectively at New Orleans, write clearly and the student should have no difficulty in grasping the essentials of electrocardiography from their book A full description of the theoretical basis will be valued by those interested, but since this aspect of the subject is still largely hypothetical it may be omitted by those who are not Just the right number of tracings are reproduced to balance the text The common abnormalities of the cardiogram are first described according to topography and in a later chapter in relation to ætiology The recent work incorporated in the book has been well selected

Dictionary of Scientific Terms

(2nd ed) C M Beadnell MRCS, FZS London Watts and Co Pp 232 2*s*

Anyone who reads much modern scientific work must inevitably, from time to time, meet words unknown to him, and inadequately defined or not to be found in an ordinary dictionary To give some help in this difficulty Admiral Beadnell has compiled this pocket dictionary It will seldom be found wanting, and the ingenuity and terseness of the explanatory information are impressive It is rather terrifying that the growth of science should have minted such various and often monstrous coinages to express its ideas, especially since each new advance makes still more new coinages necessary and at the same time banishes many previous terms from circulation! Thus much of the vocabulary at present in vogue is likely to be incomprehensible to future generations extensive use of local sulphonamides **WOODS**[13] has shown that in vitro procaine is a potent inhibitor of sulphonamide activity The rapid absorption of the local anæsthetic the fact that it is really placed in the abdominal or mesentery layer and not in the cavity itself probably discounts any such action but no experimental work on this aspect has yet been recorded Finally, there is a tendency to regard the abdominal wounded as hopeless and the time as better spent in attending to other casualties Some belly wounds by the nature of the injury must be mortal, but **GORDON-TAYLOR**[14] has reviewed a series of over 600 cases that reached the operating-table, and half of these survived That makes abdominal surgery worth while

SULPHONAMIDE-RESISTANCE

THE development of resistance to sulphonamides is dramatically illustrated by a case reported from Cincinnati, where the subject has been given much attention by **SCHMIDT**, **SESLER** and others[15] A patient suffering from pneumococcal endocarditis was treated by repeated courses of sulphapyrazine At first the organism was quite sensitive to the compound in vitro and the patient responded definitely though temporarily, to each course but the organism s resistance gradually increased, as shown by in-vitro tests, until eventually it resisted high concentrations of the drug and no further clinical response to the treatment could be obtained The history shows the course of events when an organism is maintained in long but ineffective contact with a sulphonamide compound This phenomenon forms a close parallel to the well-known development of arsenical resistance in the trypanosomes of African patients treated unsuccessfully with tryparsamide

Besides its theoretical interest drug-resistance is obviously of great clinical importance[16] It has been described in streptococci pneumococci and gonococci, and it may be expected to develop in any organism which is initially sensitive to sulphonamides When it occurs, it extends to all compounds of the group, although an organism which resists the weaker bacteriostatic action of sulphanilamide may sometimes succumb to a more active substance such as sulphathiazole , on the other hand the resistance does not extend to bacteriostatic compounds of a different type such as penicillin or gramicidin[17] It is not known with certainty how quickly resistance may develop in clinical practice, but the laboratory evidence suggests that development may be rapid Thus when pneumococci were passed through mice treated with insufficient doses of sulphapyridine resistance was much increased after 7–15 days, and after 13–23 days it was maximal , when pneumococci were cultured in weak concentrations of the same compound in-vitro resistance was raised within 80 hours[18] In the case of endocarditis referred to the first serious increase of resistance took place between the 31st and 71st days, and according to **HAMBURGER** and his colleagues there is less hazard of resistance developing during short intensive treatment such as is given for lobar pneumonia **FRISCH**[19] reports that strains of pneumococci isolated from patients after chemotherapeutic treatment were definitely more resistant than those isolated before it , this might be due either to the weeding out of sensitive strains or to an acquired resistance **FRANCIS**[17] has recorded a minor epidemic caused by a sulphanilamide-resistant strain of streptococci in a plastic-surgery ward There was no evidence to show whether the resistance of this strain was spontaneous or acquired during treatment, but the conditions of a wound dressed daily with sulphanilamide, which often diminishes the infection without destroying it completely are clearly favourable to the development of resistance To prevent the spread of such resistant organisms a rigid dressing technique is essential

Once a strain has become maximally resistant it can maintain its resistance for long periods[20]—**SCHMIDT** and others[18] found that it was not diminished by passage through 200 mice or by repeated subcultures in vitro—so that the same lack of clinical response may be expected in all the patients who have become infected, directly or indirectly from the original source There is some evidence that sulphonamide-resistant pneumococci persist in the nose and throat of patients as long as four months after the clinical cure of pneumonia It seems possible however, that strains which are *only* partially resistant may revert to their original sensitivity Some of the sulphonamide compounds are more apt to provoke resistance than others Sulphanilamide does so most readily, sulphapyridine less readily while sulphathiazole is the least liable of the three[20] It may be that streptococci become resistant less readily than pneumococci, on which most of the work to date has been done When sulphonamide-resistance does occur it is important to recognise it at an early stage so that the patient is not uselessly subjected to the toxic effects of further sulphonamide treatment The primary indication will be the absence of the expected clinical response, but when resistance is suspected it may be confirmed by various procedures—e g , a culture of the organism (streptococcus) may be smeared across a plate, part of which contains sulphanilamide,[17] or the sputum from a case of pneumonia may be injected intraperitoneally into mice treated with sulphapyridine and into control untreated mice, the presence or absence of resistance being shown within 18 hours by the rate of multiplication of the organisms in the peritoneal exudate[21] When resistance has thus been confirmed it is useless to continue with the sulphonamides and other measures have to be adopted In cases in which resistance is not initially present every effort should be made to avoid producing it by faulty therapy Small ineffective doses should be eschewed and intensive courses of treatment given from the beginning (with due precautions against urinary blockage) if the expected response is not obtained in a few days the treatment should be discontinued Treatment continued over a long period besides being responsible for most of the toxic manifestations, will almost certainly produce drug-resistance The nature of the change which underlies drug-resistance is obscure The morphology, cultural characteristics and virulence of the years ago LAHEY's[1] mortality for radical partial gastrectomy was 18%, now it is less than 1% (1 death, from pulmonary embolus, in 154 operations), and he hands the credit for the fall to the improvements in anæsthesia. To fail to apply these principles to the treatment of the wounded abdomen would be irrational. But that does not mean that one "standard" type of anæsthesia is to be employed for every abdominal operation.

LAHEY and many surgeons in Britain use light or heavy spinal anæsthesia for their abdominal operations. Colonel J DAVIS,[2] writing in the *Military Surgeon*, and STORCK,[3] who took part in a special American panel discussion on abdominal trauma, regard spinal anæsthesia as the most suitable for the wounded abdomen. Few in this country will, however, countenance this in the presence of shock, and GORDON-TAYLOR[4] goes as far as to say "Spinal anæsthesia spells certain euthanasia for the shocked abdomen." The work of O'SHAUGHNESSY and SLOME[5] is often quoted in support of spinal anæsthesia; for they showed that in the experimental fractured femur of cats shock could be delayed or favourably influenced by this procedure, but they made a special point of stressing that it was dangerous to apply this reasoning to all types of shock, and especially that following trauma of the intestines. It is also dangerous to argue that the fall of blood-pressure in spinal anæsthesia does not matter and may be checked by suitable injection. In the unshocked patient the fall does not produce, nor is it associated with, any reduction in the circulating blood-volume.[6] But in shock the transport available to carry oxygen to the vital centres is reduced and the pallor, coldness and generalised vasoconstriction are all part of Nature's rationing scheme. Forcibly to dilate unimportant blood-vessels with a spinal anæsthetic is sabotage of the transport system. JULIAN SMITH,[7] writing of his Libyan experiences, pointed out that a large vessel, usually in the mesentery, is almost invariably severed in the wounded abdomen. The anæsthetist should constantly visualise this large vessel, for the time to operate is often left to his decision.

To delay anæsthesia in the abdominal wound in the hope that shock will improve with time is a form of wishful thinking that still needs checking. The vital centres are damaged early, and unless the bleeding is stopped early resuscitation measures will not catch up. That hæmorrhage is one of the most important factors in the production of abdominal wound shock is shown by comparison with other abdominal injuries. The patient with a stab wound, with severed bowel only, usually looks quite fit; the man with a ruptured bowel, with no penetration of the abdominal wall and no vessel damage, shows for several hours little alteration in pulse or blood-pressure—as MASSIE[8] and ESTES[9] have pointed out, there is a striking absence of symptoms indicating mortal injury for two hours. The importance of early operation for the wounded abdomen has also been urged by Russian surgeons. Following the work of VISHNEVSKIY[10] they maintain that with local anæsthesia operation can be started even while the patient is in a state of shock, and PSHENICHNIKOV of Moscow[11] even says that as the mesentery is being injected the shock passes off. Using two operating tables they noted a striking difference between those under general and local anæsthesia. They used 0·25% procaine (sodium chloride 5, calcium chloride 0·125, potassium chloride 0·075, procaine 2·5, distilled water 1000 parts). After local infiltration and generously saturating both recti, the abdomen was opened and the parietal peritoneal surfaces widely infiltrated. A presenting intestinal loop was then pulled out, the mesentery injected and the infiltration gradually advanced so as to bathe the entire mesentery root in procaine solution. For the upper abdomen infiltration of the mesocolon down to its base was also necessary. The abdomen was thus absolutely relaxed, and a full laparotomy and intestinal suture took from 40 minutes to an hour; no ileus was observed, and since the patients were conscious their subsequent evacuation was not held up. Blood transfusions were given in many of the cases, and intravenous glucose was used postoperatively.

Local infiltration anæsthesia, often combined with a splanchnic block, is used by many surgeons, but most British surgeons also have the patient asleep. Almost every general anæsthetic carries some danger or disadvantage, but consideration of the psychological make-up of the shocked patient is an important part of treatment. The average Englishman prefers, and as a rule demands, to be unconscious for what is otherwise an ordeal to him and even to the surgeon. The great advantage of the local anæsthetic is that it permits of the lightest possible plane of narcosis; this is especially important on the battlefield where orderlies, and even the padre, have had to be coopted. In the city battle zone, cyclopropane, with which oxygen percentages of 75–90% can be given, is widely preferred as the complementary anæsthetic; it is now readily obtainable but its administration is probably best left to the skilled anæsthetist. Nitrous oxide with oxygen is usually quoted as the safest anæsthetic, and for that reason is often picked by the not so expert. But it is almost impossible to maintain unconsciousness with it without suboxygenating the patient, and in shock maintained anoxia is particularly dangerous. There may be little indication of this oxygen lack, for if there has been hæmorrhage and the hæmoglobin is below 50% *no external cyanosis will be observed.* Ether has shown the greatest safety in the greatest number of hands providing it is used for narcosis and not for relaxation. With the abdominal wall relaxed by local injection, the intravenous barbiturates have much in their favour and anæsthesia may well be started by injecting one of these into the rubber tube delivering a blood-transfusion. MALLINSON,[12] who has investigated casualty anæsthesia in the EMS, finds that with intravenous barbiturates "shock is not a contra-indication; properly administered, in fact, the reverse is outstandingly clear." Local anæsthesia has one possible disadvantage, important these days with the

Schools Association, have contributed much to this subject Their pamphlet The Control of Measles issued in 1913, was of great value in the struggle for sanity In addition they have revised their Code of Rules many times since its first issue in 1885, their latest (10th) edition was published in 1940 This Code was written mainly for public and preparatory schools, but it is full of information on infectious disease as a whole The official memo notes that medical officers in some urban areas recommend that the practice of allowing contacts of measles german measles and chicken pox to attend school might be extended to include those of any of the common infectious diseases of childhood except on the rare occasions when there is some special reason why an individual child should be excluded These medical officers feel that the attendance of contacts at school makes their daily supervision by the school medical and nursing staff easier and facilitates the early detection of fresh cases

POST-ARSPHENAMINE JAUNDICE

In the past eighteen months there has been a widespread impression that syphilitic treatment is too often being complicated by jaundice No figures have so far been published to substantiate this view and it would be useful if the Services would publish their experience Various factors prevent an accurate estimate of the incidence, but most of them have been operative in the past also and would not vitiate the comparison The differential diagnosis in such cases is by no means easy for in addition to liver damage by spirochætes and arsenic, the syphilitic patient is at least equally exposed to the other disease processes which may produce jaundice Infection of the liver in early syphilis is probably common but seldom shows itself clinically and tests of liver function have hitherto contributed little to the detection of subthreshold hepatic syphilis Once treatment is well established it is difficult to believe that subsequent jaundice is syphilitic in origin since the arsphenamines are stored in the liver According to Mathieu[1] 40% of the drug remains in the body seven days after intravenous injection Bulmer[2] states that more arsenic is excreted in the fæces than in the urine the bile being the main channel of excretion, and arsenic has been found in the bile 25 minutes after the intravenous injection of neoarsphenamine[3] Jaundice occasionally appears after the initial one or two injections and in such cases is probably due to a Herxheimer reaction More usually it develops after 8–12 injections and the arsphenamines are probably contributory in such cases Moreover, the incidence of jaundice developing during the treatment of syphilis has increased since the introduction of the arsenobenzene preparations, in cases treated with arsenicals the reported incidence of jaundice varies from 0 6%[4] to 5%,[5] while the extremes for untreated syphilis are 0 18%[6] and 0 37%[7] There has been no evidence to correlate cases of postarsphenamine jaundice with the use of any one arsphenamine preparation or with any particular batch of drugs In 1920, Stokes and his colleagues[8] expressed the view that the icterus was due to infectious hepatitis unrelated to syphilis or to the arsenicals and since the confirmatory epidemiological work by Ruge[9] in the German navy this view has become increasingly accepted Roholm and Iversen[10] have shown by biopsy that infectious hepatitis is a diffuse hepatitis, and Andersen[11] has demonstrated that the virus responsible is pathogenic for swine and transmissible from man to swine and from swine to swine 5 of the cases in which Roholm and Iversen performed biopsy developed jaundice during or after treatment with arsenobenzene compounds and the histological changes in the livers of these patients did not differ from those found in other cases The signs symptoms and clinical course are also similar and it is reasonable to suppose that many cases of postarsphenamine jaundice are due to virus infection the resistance of the liver having been impaired by the toxic action of the arsphenamines Epidemiological studies of infectious hepatitis[12] suggest that the disease is probably transmitted by droplet infection that the incubation period is between three and six weeks and that patients are infective early in the disease and cease to be a danger to others within a week of the onset of symptoms In view of the early infectivity and the occurrence of mild and undetected cases epidemiological control is difficult War conditions favour the spread of infectious hepatitis and localised epidemics among Service and war-factory personnel may well occur

ARCUS SENILIS

A GREY annular opacity just inside the corneal circumference, is seen in almost all elderly people Its name is unfortunate for it implies a senile change, and thus when found in those under the age of 40 as it often is, suggests prematuresenility In these younger patients it might better be termed arcus presenilis or juvenilis It never causes symptoms or interferes with vision and has roused only occasional academic interest The first histological examinations were made by Canton[13] in 1850 His findings were confirmed by Virchow in 1852 and His[14] in 1856 who found the lesion to consist of intracellular globules and considered it a fatty degeneration Since then several other views have been put forward but Rohrschneider[15] and Lowenstein[16] have now confirmed that it is a lipoid infiltration and have produced it in animals by feeding them on a cholesterol-rich diet Histologically the fatty droplets are intracellular, the smallest being in Bowman s membrane where they produce the sharp edge which, as can be seen clinically leaves a clear ring of cornea between the opacity and the corneal circumference In the deeper layer the droplets are both intracellular and extracellular and run right up to the corneal margin Clinically the arcus is of no consequence but at operation it may occasionally cause the surgeon to doubt where the cornea ends and the sclera begins Following up a statement by Rohrschneider that it is usually a sign of arteriosclerosis elsewhere in the body Rintelen[17] has carried out an investigation at the Institute of Morbid Anatomy in Basle In 600 autopsies he found that a macroscopic arcus senilis existed in 214 and that there was no sign of arteriosclerosis in 66 of these (31%) In 97 (45%) there was a moderate arteriosclerosis and in the remaining 51 (24%) it was severe In 39 all over 60 years of age there was no arcus, though 13 of these showed severe arteriosclerosis and 7 of them had died of a vascular lesion The arcus was found 4 times in patients under 50 and in none of these was there macroscopic or microscopic evidence of arteriosclerosis Since arcus senilis and arteriosclerosis both arise in elderly people, it is natural that they should often be seen together in the same patient but from Rintelen s investigations is organisms are usually unchanged Arsenical resistance of trypanosomes is apparently due to a diminished affinity of the parasite for the drug, but in the case of bacteria there is still no evidence for an explanation along these lines, and it seems probable that the phenomenon is somehow related to *p*-aminobenzoic acid Too gloomy a view should not be taken of the difficulties which sulphonamide-resistance may cause Although examples are now more often reported, the great majority of streptococcal, pneumococcal and gonococcal infections still respond to sulphonamides Some fear that all the strains of these organisms will eventually be made resistant, but acquired arsenical resistance has not yet progressed far in Africa And even if sulphonamide-resistance does eventually become widespread the recent work in Oxford[22] suggests that by then we shall have other weapons in our hand

Annotations

THE NF IS DEAD

THE Ministry of Health reminds us that the National Formulary was superseded by the National War Formulary on Dec 1, 1941 Apparently some practitioners are still prescribing mixtures from the NF for their insured patients with consequent inconvenience to patient and pharmacist, and often wastage of drugs which are scarce The ministry urges doctors when prescribing medicines by title alone to use those titles included in the BP, BPC or NWF but no others

NUTRITIONAL SURVEYS IN INDIA

IT is a relief to turn from the accounts of India in the daily press and take up Memoir 34 of the *Indian Journal of Medical Research* This deals with a series of investigations carried out in India by Dr D C Wilson between 1936 and 1940 The diets of Indian communities in Kashmir, the Himalayan foothills, the Punjab, Hyderabad (Deccan), the Central Provinces and Orissa were investigated These areas were chosen partly because they were centres of considerable nutritional disease and partly because they were representative of the great rice, wheat or millet eating areas of the country The heights, weights, teeth and physical condition of thousands of Indian children in the same areas were examined at the same time Subsidiary studies were also made of the health of the inmates of various jails and of leper asylums Of the many facts of outstanding interest brought to light, one of the most arresting is that Indian children seem to be both shorter and lighter at all ages than their English or American fellows Among the Indian children themselves the Hindus tended to be both shorter and lighter than the Moslems or Sikhs One wonders whether these differences would disappear if all the diets could be equalised from birth The diets of all the poorer Indian communities fall short of the standards set up by the League of Nations, and it was found also that, as in this country, poverty is the great obstacle to an adequate diet Contrary to common belief, income rather than religion determines what an Indian shall eat An interesting point is made that localities in which wheat can be grown are also favourable for the production of other valuable foods such as milk, and it is to these rather than to the staple cereal that differences in physique are likely to be due Comparisons were made of the incidence of rickets and osteomalacia in communities with very similar diets, and the great differences are attributed to the exposure or otherwise of the body to sunlight It will be chastening to some who flatter themselves that they are hard workers to brood on the amount of travelling and trying work which the collection of these data must have involved It is pleasant also to ponder over the personal and private Anglo Indian goodwill which made it all possible Those who know anything about dietary surveys, however, will realise that the field work was only the beginning The analysis and presentation of the data, which seems to have been carried out by Miss Widdowson, PhD, must have been as great a task, though an unostentatious one

SCHOOL CLOSURE FOR INFECTIOUS DISEASE

A MEMORANDUM[1] issued jointly by the Ministry of Health and the Board of Education says in big type "The principle relating to the closure of schools enunciated in the memorandum, that it is only in special and quite exceptional circumstances necessary to close a school in the interests of public health, still holds good " After years of controversy this principle has at last been established One of the first steps towards this end was the Woolwich inquiry which was planned in 1902 to last for five years The utmost possible school closure was followed in the eastern half of the borough and class closure only in the western half After some years Dr S Davies reported that while more cases were notified in the non closure districts, closure had no appreciable effect on the age incidence and that the death rates in both districts were about equal He concluded his report in 1906 " There is no doubt that in a large proportion of cases the infection of measles is contracted at school, and brought by children attending school to the younger members of the family not attending, among whom measles is so fatal Now, obviously, if the age of school attendance were raised by one or two years the number of young children, none of whom attended school, would be increased in proportion, and a large number of young children who are now exposed to the risk of infection would be comparatively safe " Dr James Kerr says in his book Fundamentals of School Health " I have always disagreed with this doctrine " Six years later the *Lancet*,[2] speaking of the compulsory attendance of contacts at school, comments " It is incredible that any body of intelligent authorities should countenance a proceeding so fraught with danger to the entire community " Another step was taken in Birmingham, where notices were sent to parents of unprotected children to keep them at home if there was any appearance of illness This was good health propaganda C J Thomas stated in School Hygiene (1913–15) " the history of measles epidemics proves that, given a sufficiently unprotected population, measles will spread whether there be schools or whether there be none " Kerr made a similar observation on his experience of measles in Bradford, and said that the school is not the main agent in diffusion He goes even further and maintains that " all the isolation, exclusion or disinfection possible does not postpone the incidence of measles in 10% of those liable by more than five or six months " In 1919 the committee of the American Medical Association and the (USA) Bureau of Education reported that " the closure of schools is an extremely clumsy, unscientific and unsatisfactory method of controlling epidemics among school children It results not only in loss of school time and money, but it fails to control, inasmuch as infected children are at large playing in the street without restriction and therefore spreading the infection " This was twenty three years ago So at last we progress In 1923 there was an epidemic of scarlet fever in Islington which continued throughout the period of the holidays when the schools were closed, and school infection cannot therefore have played any considerable part in the dissemination of infection[3] The Medical Officers of

SUPERVISION OF SICK ABSENCE IN INDUSTRY

SIR HENRY BASHFORD M D LOND, F R C P
CHIEF MEDICAL OFFICER TO THE POST OFFICE

BEFORE the war some large firms—though relatively few—had already recognised the value of employing medical advisers whole- or part-time and of keeping staff sick records Since the war many more such advisers have been employed in Government and other factories and there has been a general recognition of their value not only to employers, whether state or private, but to employed But there is probably still a residuum of suspicion among many workers and their unions and associations that these medical services are mainly of a police character, and have the object of scenting out malingerers and slackers and of bringing ill or injured employees back to work at the earliest possible moment—perhaps too early—in the interests of output or the maintenance of profits

Where departments or firms pay their employees while they are away from work owing to illness, or where they are paying compensation for accidents incurred on duty, or illness due to occupational causes it would be generally admitted that the employers have a right to their own medical adviser's opinion about the genuineness and nature of the illness and the prospects of either full recovery or ability to perform, if available some lighter form of work There may too have been managements and medical advisers with what psychologists might call a malingerer complex but few people with a wide experience of industrial sick absence and of industrial medical officers would agree either that malingering is common (in the true sense of the word *it is exceedingly rare)* or that industrial medical officers as a body are malingerer-hunters or capable of being bought by their departments firms or industries to the extent of failing to give honest medical advice Most doctors in industry are concerned to see that the staffs of all ranks under their care are as healthy and happy as possible employed in the right sort of job for their particular physical and mental abilities and working in the best conditions practicable

It has been argued that all this can be left to the employee's private or panel doctor who knows—or should know—better than anybody else his patient's particular physical and mental make-up and domestic circumstances, and who being an outside independent doctor is less likely to be biased in his estimate of his patient's working capacity There are clearly contributions that he is the best person to make but the industrial medical officer has—or should have—data not generally available to the private or panel doctor He should have accurate sick records perhaps extending over many years and including absences from work that may not, owing to their brevity, have been medically certificated He should have intra-departmental or intra-factory or intra-office knowledge, not available outside, of how a man or woman or boy or girl reacts to the work in hand and the environment, physical or personal in which it is performed And he is—or should be—in a position to secure modifications of work or environment which may make considerable difference to health and efficiency In other words he should be the supplement not the antagonist of the private or panel doctor and both should be the friends and confidants of those under their mutual care

The essential basis of supervision of sick absence is the maintenance of accurate individual sick records in such a form that they can be studied at any time by the industrial medical adviser and that the average annual sick absence per head of staff can be regularly recorded Thus an adequate picture can be obtained of the history of working capacity of any employee and of a whole department or industry The working-capacity medical history may not always be synonymous with the clinical medical history Thus many hospitals and doctors keep a follow-up, record of various groups of cases by interview or letter they learn from their patients of the presence or absence of signs or symptoms and base on this their views of the success or otherwise of some operation or form of treatment But they can seldom gain by these means such an accurate picture in terms of actual working capacity as a department, or works or industry can—or should be able to—from its own day-to-day and year-to-year sick records Such records can bring into a much truer perspective the actual effect on workaday life over a long period of some operation treatment, or real or supposed physical defect or disability Examples of this in the cases of gastric and duodenal ulcers [1] pulmonary tuberculosis [2] adolescent albuminuria,[3] *contacts with zymotic fevers* [4] and other conditions have been given in previous papers and many more long-distance, large-scale observations of this kind should be obtainable from industrial sick records The supervision of sick absence in industry should thus be capable of making essential contributions to the advance of general medicine and surgery

* * *

It is perhaps in the great field of minor maladies—in which temperament anxiety lack of a sense of responsibility maladjustment and physical ill health meet and mingle and influence each other most—that the supervision of sick absence in industry can play its most valuable part and give an *opportunity* for preventive medicine The sick absences of two or three days, or less than a week are probably about four times as frequent as those of a week or more, although this may not—perhaps owing partly to the present form of panel certification—be reflected in the statistics of sick absence under the National Health Insurance scheme Many of these short sick absences may be due to organic causes, such as decayed teeth or septic tonsils a lack of resistance to some particular common pathogenic organism, or some form of minor chemical allergy , and the proper routine supervision of sick absence should give the industrial doctor the opportunity of suggesting an appropriate remedy But there will remain a considerable number (though a minority) in any large staff of employees with an abnormal yearly record of minor sick absences for which no obvious organic basis can be found And it is among these that the industrial doctor —provided he has sympathy and common sense and the insight that grows with experience—can be most valuable, especially to the young

Over and over again he will find some such factor as groundless anxiety, thwarted or seemingly thwarted ambition some personal antagonism real or fancied to a particular job or fellow-worker or foreman or office superior and he will be able to make an adjustment which results in an immediate and permanent alteration in the sick record Or he may find some factor of irresponsibility not of malingering in any serious sense, but of a too light-hearted taking of a day or two off for medical or semi-medical reasons Few people and especially young people, memorise their own sick records , and many when confronted with them in black and white are genuinely surprised by their extent often a complete alteration is the result If there is no change and no definite physical or psychological cause is discovered for repeated minor sick absences a kindly intimation that if the record continues as in the past the question of retirement or discharge on medical grounds will arise may have a considerable effect This was illustrated in a group of workers on whom I have previously reported [5] Over about 4 years this group of 40 people mostly young, had incurred between them 736 separate sick absences, totalling 6194 days after receiving the intimation described these 40 people during the next six months only incurred 54 days' sick absence their six-monthly average of illness dropping from 19 days a head to 1 3 It would be unfair to describe supervision of this sort as medical police-work in any vindictive sense since it was clearly of benefit not only to the departments but to the workers concerned and it may be that such supervision may prevent the development in later years of a valetudinarian outlook on life much harder to combat In any large staff, there will also probably be cases in which the real reason for continued minor illnesses is a fundamental dislike to the particular occupation In such cases, medical advice to seek some other mode of life is probably in the truest interest of the employee

In the exercise of medical supervision of sick absence, the industrial doctor will soon come to appreciate the importance of lay supervision by foremen forewomen heads well as from clinical experience it is safe to say that the possession of an arcus senilis does not mean its owner has vascular disease

VENOUS OBSTRUCTION IN VOLKMANN'S CONTRACTURE

THOSE who have held that venous obstruction is the most important factor in the production of Volkmann's ischæmic contracture have based their belief largely on a supposed special vulnerability of the communication between the superficial and deep venous systems around the elbow If as has been held the communication depends on one small venous channel lying deeply in the antecubital fossa, it is easy to visualise its complete interruption by the compression of swollen and bleeding tissues, and particularly by a subfascial hæmatoma In a series of careful anatomical studies Horwitz [1] has demonstrated the variations that can occur in the communications between the deep and superficial venous systems at the elbow He has shown that there are three distinct collateral veins or venous networks in addition to the so called communicating vein By injecting radiopaque medium (30% sodium iodide) into the upper extremity of 10 cadavers, a series of complex networks was demonstrated additional to the four communications which were large enough to be made out by gross dissection The sodium iodide injected into one of the radial or ulnar veins appeared immediately in the arm above the site of ligation Injection was practised not only with an intact venous system but also after ligation of the communicating vein just distal to its termination in the cephalic or median cubital vein, and of the brachial veins just above the site of their formation The solution, despite these obstructions immediately entered and coursed up the arm in every instance Horwitz concludes that a good collateral venous circulation normally exists in the elbow region, well protected by muscle planes and external to the confines of the antecubital fossa The anatomical basis of the venous-obstruction theory of Volkmann's contracture is thus undermined That sudden experimental venous occlusion may produce a condition resembling ischæmic contracture can perhaps be explained through a vasomotor reflex There is now sufficient evidence that trauma to an artery can produce reflex ischæmia and the otherwise inexplicable ischæmia of the white leg of venous thrombosis has also been regarded as evidence of this reflex mechanism

CHRONIC INFLAMMATION

SO CALLED chronic inflammatory tissue, of no discernible origin, is often encountered in human pathological material, and it is generally assumed that the cause—whatever it is—is extrinsic and that the agent responsible should be identifiable in the inflammatory tissue itself Pullinger and Pirie [2] have obtained evidence to suggest that non specific chronic inflammation may be intrinsic in origin and more subtle than is usually suspected and that it may persist for a long time after the visible causative agent has disappeared They made a series of implantations of sterile purified collagen from the cornea of the ox between the dermis and the panniculus carnosus of rabbits Biopsy specimens were removed at weekly intervals and a more or less continuous histological picture of the cellular reaction was so obtained The implants were rapidly surrounded by a cellular and fibrous vascular capsule which by the end of the fourth week began to fill up with large foamy macrophages accompanied by lymphocytes and plasma cells Collagen fibres had disappeared by the fifth week, but the macrophages contained fragments of material responding to collagen stains and these persisted without significant change until the end of the third month, which is as far as the investigation was carried After making allowance for minor differences between rabbit and human cytology, the general histological picture after the fourth week, when the collagen fibres disappeared, was closely comparable to that seen in human non specific inflammation Collagen is a highly resistant substance it is no more than feebly dissolved by any known proteolytic enzyme which works within the neighbourhood of neutrality Pullinger and Pirie suggest that it is the relative insolubility of the collagen that is responsible for the reaction and its persistence, and that an alteration in the physicochemical properties of the subject's own less soluble structures may in certain cases initiate it They do not think that the heterologous origin of the collagen played a significant part in the reaction though ideally a control using homologous or even autologous collagen implants would have been desirable Their paper has a bearing on skin grafting, since such grafts contain a high percentage of collagen and are often laid directly on the surface of granulation tissue

PROPHYLACTIC TETANUS ANTITOXIN

THE War Office reminds medical officers[1] that tetanus antitoxin should be given to all battle casualties even though they have had tetanus toxoid in the past or tetanus antitoxin recently It should also be given to patients suffering from any wound which seems likely to be infected with tetanus When antitoxin is given subcutaneously a maximum level in the blood is not reached for 3–4 days, whereas if it is given by deep intramuscular injection the same or a higher level is reached much more rapidly, appreciable quantities of antitoxin being demonstrable in the blood within a few hours Deep intramuscular injection—into the deltoid, the subscapular or outer quadrant of the gluteal regions—should therefore be the normal route , intravenous administration is not recommended *for prophylactic use*, because of the possibility of anaphylactic reaction The minimum dose should be 3000 units, but this should be doubled or trebled where there are very foul lacerated wounds If there is documentary evidence of active immunisation with tetanus toxoid a single dose of antitoxin is sufficient, otherwise two further doses of 3000 units should be given at weekly intervals

SURFACE FREEZING FOR DEEP PAIN

THE views of Leriche on the value of local anæsthesia in promoting recovery from simple ligamentous and muscular injuries are now widely accepted The abolition of nervous impulses from the damaged structure interrupts the vicious circle of reflex muscle spasm, vasodilatation and œdema and accelerates return to normal function Two papers in this issue describe the benefits of freezing the skin with ethyl chloride when dealing with *underlying painful lesions of soft* tissues periarticular structures or even chronic joint affections and fractures Henry describes striking relief in a variety of cases, while McIntosh and Petrie, writing from a Canadian hospital in Britain, record similar results in minor injuries, particularly around the ankle-joint, in soldiers There is no doubt that the method works, but explanations of its action are lacking Henry demon*strated by inserting a thermometer* into the thigh that the chilling does not reach deep structures, and his happy experience with a colleague's dachshund seems to rule out the element of suggestion The now established work of Kellgren [2] on pain referred diffusely from muscular and ligamentous foci seems relevant It is possible that anæsthetisation of the superficial area of reference by freezing may abolish the pain, as in the classical though disputed experiments in which referred pain of diaphragmatic origin was abolished by infiltrating the skin of the shoulder with procaine But this is another of those well-founded clinical observations which still await the elucidation of careful scientific research n the latter, though still further effort should be made n the direction of pooling

Indian Medical Service—The committee asked the CMWC to make every endeavour to supply a specified number of medical officers a month to meet the demands of the IMS Compulsory powers could not be exerted to compel doctors in this country to accept service in the IMS, but the Government of India had introduced liberal concessions regarding antedate &c , for candidates in India, and it was hoped that the application of these concessions to candidates in Britain, would result in a satisfactory supply If volunteers for the IMS were not forthcoming, it would be necessary to make up deficiencies by the supply of additional RAMC officers Difficulties had arisen in regard to the service of RAMC officers with formations of the Army in India because of the reduction of the pay of such officers, when serving outside India, to British rates, but this policy had been changed and the War Office and India Office had agreed on the conditions under which the Army in India might draw to a larger extent on the RAMC

Emergency Medical Service—The committee considered that the extent and basic principles of EMS organisation should be reviewed in view of the additional functions it had acquired and the cuts in hospital staff The committee suggested that it should be possible, without running unjustifiable risks, to reduce many of the establishments and even close a number down altogether There were a considerable number of civilian mobile teams but few appeared to have been used The whole-time staff of all hospitals should be more mobile and each region should prepare schemes to secure the greatest degree of cooperation and interchangeability between the medical units of the civilian and Fighting Services

Ambulance Trains—The committee had examined the organisation for the evacuation of casualties by ambulance trains under the EMS scheme, but were of the opinion that the use of whole-time doctors for such trains, even when they were unsuitable for the Forces, was uneconomic and unjustifiable Part-time medical officers carrying out other duties near the places where trains were normally located should be used for this purpose

Current Needs of the Three Services and IMS—The requirements of the three Services and the IMS which the committee had approved for the first three months of 1942 were greater than the CMWC could hope to meet from the normal sources of supply The committee had asked for returns of the medical establishments of all civilian hospitals and medical institutions, and these showed that reduction of medical staffs was feasible in all types of hospitals, that London hospitals were more generously staffed in all categories than Provincial ones , and that a proportionately more drastic reduction was possible in mental-hospital staff The committee therefore proposed a reduction in the whole-time medical staff of non-teaching hospitals other than mental hospitals by 10% in the Provinces and 15% in London, teaching hospitals to reduce their staff by half these percentages , a reduction of 100 in the medical staffs of mental hospitals , and a restriction to 6 months of " A " appointments These proposals were incorporated in resolutions dated Nov 19 and Dec 3, 1941, and action was taken on them

Other Sources of Supply—The committee was satisfied that most of the employable alien doctors had already been absorbed into various appointments, and that it was unlikely that this source would help further in the problem of man-power

On a recent visit to the United States and Canada Surgeon Rear-Admiral Gordon-Taylor had discussed the possibilities of a further supply of doctors from those countries He thought that no more doctors would be forthcoming under the American Red Cross scheme, but that Canada might possibly make some further contributions A number of doctors from the RCAMC had been seconded to the RAMC but the committee considered that no more doctors were available from the Dominions, which already had heavy commitments for their own armed forces

The committee's suggestion of raising the age of conscription for doctors above that for the rest of the population had been partly met by the National Service (No 2) Act of Dec 18, 1941, but some time must elapse before it would produce an effective supply The committee hoped that as a result of the proclamation all doctors between 41 and 51 would be registered in one group as soon as possible , it was important that women doctors within the age-group 20–30 should be brought under the same compulsion as applied to male doctors

After scrutinising the establishments of the Public Health and School Medical Services the committee thought that by closer cooperation or otherwise these services could release more medical officers of both sexes for the Forces and passed a resolution urging the Minister of Health to consider this source of supply on Jan 7, 1942

Other possible ways of economising in personnel were brought to the committee's notice It recommended that more transport should be made available for medical officers in charge of troops so that one MO could do more work A reduction in the number of recruiting medical boards was considered, but the contribution which this could make to economy in medical personnel was thought to be negligible It did not seem that any material economy in medical man-power would result from the suggested transfer of certain EMS hospitals to the Army, but the committee approved the project because it was assured that it would be of real value to the Services in providing improved training facilities and opportunities for clinical experience

General Conclusion—The committee ended its second interim report with this conclusion

> " Our investigations have satisfied us that the Services are now fully alive to the limited resources available to meet their needs and those of the civilian population and to the consequent necessity for the utmost economy in medical man power As a result of their co operation with us the call by the Fighting Services on the resources of medical personnel during 1941 was substantially reduced We hope that our recommendations for the saving of medical manpower in civilian hospitals, and the deliberations of the Regional Committees will help to solve our problem during the next six months We are, however, convinced that *continued vigilance in the economical use of medical manpower is necessary* "

The committee hoped to submit later a separate report based on the demands of the Services for the last nine months of 1942 and on the reports of the Regional Committees

In England Now

A Running Commentary by Peripatetic Correspondents

IT is easy to understand that if one is doing fairly well in a black market, or in some more licit but almost equally lucrative war-time occupation, certain transactions must be carried out without bothering one's bank manager Cash, under such circumstances, becomes the most desirable medium by which to conduct business But too much cash may become almost as embarrassing as an over-obese credit balance at the bank , some busybody or other might want to find out how it was come by Then the excess must be converted into some form of wealth, preferably one that is practically certain to increase in value under present conditions and is small enough to be relatively inconspicuous and even in last resort portable Diamonds and other precious stones fulfil all these conditions most satisfactorily I am always glad when I learn that these things are being eagerly bought at staggeringly high prices, for I have always had a sneaking belief that some day, somewhere —maybe in the USSR—such vast deposits of precious stones would be found that their prices could no longer be kept up artificially and he who held large numbers of them would be but little better off than one who had collected bits of coloured glass I should like to live to see that day I do not greatly mind if these people buy up all the postage stamps in the world nor do I mind if they sink their surplus cash in sable ermine or silver fox for I have great faith in the activities of the moth But when a vandal who has more cash than he cares to be found possessed of buys old and rare books as a financial speculation, then would I pray earnestly that all his gods should look at him sideways And this of offices or departments, or works managers It would probably be unwise that he should have any direct voice in their selection and thus come to be regarded by the staff as an agent of promotion , but he should certainly be given the opportunity of putting certain aspects of lay supervision to would-be candidates for the work, since it is on the qualities of a lay supervisor—his or her own health self-control, sympathy and tact—that sick-rates will largely depend An instance of how profoundly a change of lay supervision may work is shown by the average annual sick absence in days per head of the following five groups of workers all in one office

	MEN			WOMEN	
1st year	15 0	15 4	14 7	24 5	25 8
2nd year	16 7	14 1	23 5	35 1	39 8
Change of lay supervision					
3rd year	8 0	6 9	13 2	22 1	12 9
4th year	7 0	7 3	10 3	14 3	10 7

The change of lay supervision was not the only factor in this immediate reduction, but it was undoubtedly the principal one—the conversion of the office concerned into what the sailors call a happy ship

This is not to suggest that industrial medicine outside a few occupational diseases, is a separate and exotic art it is merely ordinary medicine applied inside an office, works or factory But it is work which a panel or private doctor could not reasonably be expected—or indeed have the necessary data—to do

TWO REPORTS ON MEDICAL MAN-POWER

In January, 1941, the Committee of Enquiry on Medical Personnel known as the Robinson Committee, made some valuable recommendations on the distribution of medical man-power between the civil and fighting services and general practice[1] the last of which was that an effective organisation should be established to settle questions of priority The Ministry of Health then appointed a Medical Personnel (Priority) Committee,[2] under the chairmanship of Sir Geoffrey Shakespeare and widely representative of civil and military medicine, to investigate " what further steps can usefully be taken to secure the utmost economy in the employment of medical personnel " and to report from time to time what should be the allocation between civil and military services of the available personnel This Shakespeare Committee has now published its first two interim reports[3] many of the conclusions of which have already formed the basis of official recommendations to hospitals and others

FIRST INTERIM REPORT

When the committee issued its first interim report, on Aug 6, 1941, it had held 25 sittings and had made a personal tour of No 4 Civil Defence Region and other areas to study the arrangements made to meet Service and civilian medical needs, besides analysing the demands of the three Fighting Services for the last 6 months of 1940 and inquiring into the medical establishments of the EMS and other hospital and health services At that time the committee had received much evidence of cooperation between the Services but it reported that the degree of cooperation varied from region to region and that much more might be accomplished if the goodwill already existing expressed itself through a recognised machinery , in few areas had a concerted effort been made to ensure the most economical use of the available medical man-power, whether Service or civil It recommended that a committee should be set up in each Civil Defence Region to include senior medical officers of the Fighting Services in that region, the regional medical and hospital officers of the Ministry of Health the liaison officer for the area appointed by the Central Medical War Committee (CMWC) and a neutral chairman preferably the regional commissioner or his deputy The task of these committees would be to review the state of medical man-power in their regions from time to time with a view to preventing underemployment and overlapping their reports, after submission to the Government departments concerned, forming a basis for recommendations by the Medical Personnel Committee itself

This report stated that it would be difficult, on the basis of the age-groups for compulsory enlistment then in force, to obtain for the Fighting Services all the male civilian doctors who could be spared, because of the uneven geographical distribution of the age-groups and a relative shortage in certain areas of male doctors under 41 In addition, there were a large number of doctors of military age in hospitals whose removal would be impracticable It was possible to transfer a doctor from one salaried post to another, but the difficulties of transferring general practitioners from one practice to another were considered insuperable on account of the personal nature of their work and the financial problems involved The committee therefore suggested raising the age-limit for compulsory military service for doctors to 5 years over that for the rest of the population So as to enable the unavoidable drain on hospital staffs to be made with the least possible loss of efficiency the committee advised the Minister of Labour to use his powers under Defence Regulations to secure that whole time staff could be transferred as desired to meet a threat of invasion or in any other period of stress

Finally, the committee recommended that the medical officers of the Anti-Aircraft and Balloon Barrage Commands should be pooled and employed on a regional basis

SECOND INTERIM REPORT

In the next six months the committee held a further 24 sessions, and periodically framed resolutions on which official action was taken It issued its second interim report on Feb 11 1942 In August 1941 this report related each Fighting Service was asked to review its establishments and requirements and submit a revised estimate in the light of the economies effected as a result of the committee's recommendations These revised estimates were discussed with the Service representatives and agreement was reached on minimum requirements after considerable economies had been effected The number of doctors supplied by the CMWC to the Services in July–September left a deficit to meet Service needs for the last 3 months of 1941 The report goes on

> " We examined in detail reports of members of the committee who visited certain Service establishments and discussed this with the Service departments We also impressed on these departments the serious shortage of medical practitioners and the importance of adequate medical supervision for the civilian population The Services appreciated the position They again reconsidered their requirements and effected further economies The Royal Air Force accepted cuts amounting to about 37% on its original demands *for the last 6 months of the year , the Army* so revised their estimates that they reduced their original demands to nearly 40% , while the Navy accepted a cut of 50% on their requirements for the last 3 months of the year We carefully considered these revised requirements and made recommendations regarding the number of doctors to be supplied for the last 3 months of 1941 to each of the Fighting Services Practically all of this number were supplied to the Services by the Central Medical War Committee by *the end of 1941 , the* deficit was made up in January, 1942 "

The committee reported that considerable economies had been effected by the three Services, and that its suggestion for pooling the medical officers of the AA and BB commands had resulted in a substantial saving

ANTHOCYANURIA FROM BEETROOT

SIR,—Physiological changes in the colour of the urine are apt to puzzle or mislead the practitioner and two cases due to eating beetroot may be worth recording. A man of 41 complained of feeling restless, tired and run down. He had noticed that his motions were loose and his urine pink. He denied taking any drugs but eventually remembered that he had had "rather a lot" of beetroot during the past few days. He had some puffiness of his eyelids, normal pulse and temperature, and except for bad teeth showed nothing out of the way. A fresh specimen of urine was of a pink-violet colour, acid, and contained no albumin or sugar. Guaiacum reaction negative. In view of the puffiness, the absence of albumin, and the fact that he had recently eaten pork sausages a tentative diagnosis of trichiniasis was made. This was later excluded and the diagnosis was cleared up by one of our dispensers who told me he had noticed the same coloration of his own urine after eating beetroot.

In *Chemical Methods in Clinical Medicine* (London, 1937) G. A. Harrison writes:

> "Very occasionally the ingestion of common articles of diet (beetroot, bilberries, blackberries, etc.) leads to peculiar colours of the urine. Anthocyanuria, due to ingestion of red beet, is an example. The writer observed a case in a boy of seven (with diabetes mellitus) due to beetroot. The fresh urine was acid and was orange pink. It turned canary yellow when made alkaline with sodium hydroxide, to become pink again when made acid with HCl. Spectroscopically it showed no absorption bands, and contained no red cells and no hæmoglobin. On discontinuing the beetroot the pink colour stopped, to reappear after giving beetroot again. A dilute watery extract of beetroot gave similar colour changes with alkali and acid. The pigment was not extracted from the urine by amyl alcohol."

The urine in the present cases gave the reactions described by Harrison. The colour disappeared on withholding beetroot and returned after more had been taken. In the first case puffiness of the eyelids disappeared in two days. I should add that this discoloration from beetroot does not invariably occur in normally and constantly acid urines (as I have proved on myself).

My thanks are due to Mr. B. F. Heap, MPS, for his assistance and incidentally for the diagnosis.

The Medical Branch, G.P.O. V. C. MEDVEI.

WORSER DOCTORING?

SIR,—I agree with Dr. Harvey. In a district like this, a town of 4000 inhabitants with a scattered agricultural community round it, I do not see how a doctor could begin to give 8000 potential patients even the attention they need, let alone the attention they want. I suppose it depends on the individual GP, but some of us find the constant making of decisions and giving of opinions, trivial or otherwise, pretty exhausting work. Personally I cannot cope with more than about 60 patients a day (including those who attend the surgery) with even rudimentary efficiency, and I cannot do that for very long at a stretch without getting abominably stale.

RUS ET URBS.

SIR,—Dr. Harvey is right when he suspects I am an urban practitioner, but he is wrong when he suspects that I am ignorant of rural conditions of medical practice, for I had considerable experience of rural practice as a locum tenens some 10 to 15 years ago, and am the son of a GP who for 25 years worked in probably one of the hardest rural practices of this country. Obviously medical working conditions in town and country practice are very different, and I admit that my letter was chiefly meant to apply to urban practitioners. It has been said that in urban districts there must be a minimum of one doctor for every 3000 of the population. I have proved to my own satisfaction that it is possible to give good service to at least 6000 potential patients in a town. In country districts these proportions are obviously out of the question. As Dr. Harvey points out, urban practitioners are in the large majority; therefore I maintain that in medical call-ups larger proportions of men should be recruited from towns. I understand that the German civilian population has to put up with a ration of one doctor per 15,000, and most of these German civilian doctors are no doubt elderly men who had been hoping for an easier life. Of course doctors in the Services do not have to work at the same concentration as civilian doctors, but when they are on active service they have to work very much harder. They can be compared to Civil Defence workers who do not have a very arduous existence when there are no air-raids in their district, but who have to work often for days on end in appalling conditions, with no respite, when the emergency occurs. Moreover, doctors in the Services have to sacrifice the comforts of home life which are a real help to a busy GP. In spite of Dr. Harvey's gentle protest I still feel justified in asserting that our profession as a whole is not pulling its weight. I am positive that I can put forward a scheme whereby a district, whether urban or rural, could manage comfortably with half its peace-time number of doctors.

Southall, Middlesex. G. N. FOX.

VESTED INTERESTS

SIR,—I cannot agree with W. A. G.'s remarks about the sale of practices. It is a fact that a doctor who buys a retiring practitioner's practice does actually take over a large proportion of his patients, both NHI and private. Some may come and some may go but the solid nucleus of the old practice usually remains. If it were not so, practices would not be saleable at the prices asked. It cannot therefore be true that the goodwill of a practice is mainly in the professional ability and personality of the doctor. I think habit is responsible for many remaining with the incoming practitioner. One hears so often remarks like "I've been coming to this house for 40 years"—that is, through a series of three doctors. Further, I think, patients have confidence in their old doctor's choice of a successor.

For myself I do not like the idea of buying and selling practices nor am I opposed to a state medical service. None the less it is true that in the past one has had to put down a certain sum of capital in order to ensure a certain annual income. Doctors are surely just as much entitled to compensation out of public funds as any other business would be if it lost capital and interest through its termination by government action.

E. M. K.

Infectious Disease in England and Wales

WEEK ENDED AUG. 22

Notifications.—The following cases of infectious disease were notified during the week: smallpox, 0; scarlet fever, 1332; whooping-cough, 1235; diphtheria, 629; paratyphoid, 8; typhoid, 15; measles (excluding rubella), 4089; pneumonia (primary or influenzal), 346; puerperal pyrexia, 172; cerebrospinal fever, 68; poliomyelitis, 19; polio-encephalitis, 2; encephalitis lethargica, 7; dysentery, 59; ophthalmia neonatorum, 86. *No case of cholera, plague or typhus fever was notified during the week.*

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Aug. 19 was 1498, including: scarlet fever, 278; diphtheria, 130; measles, 278; whooping-cough, 242; enteritis, 46; chicken-pox, 65; erysipelas, 35; mumps, 59; poliomyelitis, 2; dysentery, 30; cerebrospinal fever, 41; puerperal sepsis, 31; enteric fevers, 5; german measles, 4; malaria, 1; other diseases (non-infectious), 126; not yet diagnosed, 125.

Deaths.—In 126 great towns there were no deaths from scarlet fever or enteric fever, 3 (0) from measles, 11 (0) from whooping-cough, 20 (1) from diphtheria, 42 (5) from diarrhœa and enteritis under two years, and 7 (0) from influenza. The figures in parentheses are those for London itself.

The fatal cases of diphtheria were scattered over fifteen great towns, none reporting more than 2. There were 5 deaths from diarrhœa at Manchester, and 4 at Birmingham.

The number of stillbirths notified during the week was 199 (corresponding to a rate of 31 per thousand total births), including 20 in London.

SIR STANLEY WOODWARK has been elected master of the Worshipful Company of Barbers. He has also been re-elected for a further year to be master of the Society of Apothecaries.

be to abandon many of our activities and devote ourselves to doing nothing in particular

Thousands at His bidding speed,
And post o'er land and ocean without rest,
They also serve who only stand and wait

FRCP

PRACTITIONER AND PATHOLOGIST

SIR,—It is indeed disappointing to read your editorial statement of August 15 that when the medical student goes into practice "he soon discovers that if he wants laboratory tests done he must either call out an expensive consultant or send his patient to the outpatient department of a hospital " We have the authority of Dr Dyke that this is far from being the true position in the provinces, where in fact consultation and collaboration between practitioner and clinical pathologist does occur without the patient first having to waste time going through the OP department of a hospital I also know of at least one teaching hospital where medical students are encouraged to interest themselves in clinical pathology as distinct from merely viewing a report returned from the laboratory

Rugby R C HILL

SIR,—For some time past the pathological department of this hospital, which incidentally does the pathology for our local council, has also been open to any and every general practitioner in our district, many of whom send specimens or even bring patients direct to the pathologist We found that this was a welcome innovation to the practitioner and has been the means of giving the pathologist a clearer clinical view of the case than otherwise would have been possible A fee is charged where it is possible for the patient to pay, but inability to pay is no bar to the examination and report

J C GILBERT,
St John's Hospital, Lewisham Secretary Superintendent

SIR,—In reply to the following extract from your leading article of August 15

> "Let it be more widely recognised that the pathologist is not a technician but is as a rule a man with a wide and accurate knowledge of medicine which he is glad to put at the disposal of his clinical colleagues "

Let it be more widely recognised also that neither is the technician a pathologist, but is as a rule a man with a wide and accurate knowledge of laboratory technique and the significance of laboratory findings, which knowledge he is glad to put at the disposal of the medical profession in those hospitals where no pathologist is employed

Little Shrewley, War F GARDNER

REACTIONS TO THE REPORT

SIR,—Ultracrepidation is a most pleasant vice and during the two months that have elapsed since the publication of the Interim Report I have resisted nobly, knowing that, for one who has never been in general practice, comment is hardly seemly However, the silence of my colleagues and the reassurances of Lord Darlington have encouraged me to overcome my scruples

Few would disagree with the broad definition of the objects of medical service (Question 1, page 41), yet how is this to be achieved ? By some form of group practice with clinics or health centres, together with an extension of National Health Insurance to include dependants and enlargement of its scope by the inclusion of consultant and specialist services Before the war, general practitioners in urban areas and hospital consultants had insufficient time to look to the purely remedial aspects of their sick patients A conscientious general practitioner has told me that on an average he had only five minutes to see each patient and a hospital consultant that he had only fifteen minutes for each new outpatient, in the country the problem is a different one, for there the time spent in travelling is the major factor

It is agreed that in a medical service directed towards the achievement of positive health far more attention must be paid to the study of the environmental factors which set a disease process in train and an elucidation of these is more time-consuming than an exhibition of the clinical acumen of remedial medicine How often does a hospital patient ask to see a consultant in private, not to receive preferential treatment in hospital nor some superior brand of medicine, but in order to have an opportunity to discuss his or her problems in greater leisure and privacy than is possible in the average outpatient consulting-room ? Apart from the disadvantages to the individual patient of this rush medicine, the lack of time for the doctor to contemplate the problems of his cases, examine them leisurely and read about them, must in the end stultify the enthusiasm of any but the most resolute In medicine one's working day should at least be equally divided between routine work and thinking about it

In the report it is suggested that the provision of secretarial assistance, &c at the Health Centre would allow this needed leisure for work, naturally, properly organised working conditions would be an improvement but the real need is for a very considerable increase in the number of practitioners—at a guess an increase of 30% whereas the annual increase in registered practitioners is about 3% To achieve such an increase must involve a long-term plan of medical school expansion, &c ; but to propose the introduction of an adequate medical service both from the point of view of the people and the practitioners without an estimate of the number of practitioners required to carry it out can only lead to disappointment and a reversion to a state of affairs as bad if not worse than before, particularly when a large proportion of the profession do not realise the full implications of social medicine

It should not be thought that the institution of a whole-time salaried service (organised by the state or private enterprise) would achieve the desired result, although there are many who could work as well if not better under such an organisation, there are just as many who would rebel or become drones With regard to the administrative proposals set out in the report, the brilliant PEP broadsheet *Planning for Social Security* points out the absurdity of proposing extensions of National Health Insurance which would "become nothing more than an extraordinarily elaborate mechanism for *excluding* 10% of the total population from the panel medical services " and would perpetuate the fantastic state of affairs where a sick man may ask to be taken off "the panel " as he will receive more from unemployment relief

Oxford A H T ROBB-SMITH

"ETHISTERONE "

SIR,—I have noted with some perturbation in your issue of Aug 8 (p 174) that the General Medical Council has approved of the name ethisterone for the derivative of progesterone known as anhydro-hydroxy-progesterone pregneninolone or ethinyl-testosterone, and that its inclusion in the British Pharmacopœia is under consideration In my experience medical practitioners who have not made a special study of endocrinology are already confused by the large number of hormones and hormonal derivatives, and this confusion is increased by the number of synonyms applicable to some of these substances The addition of yet another name to a substance which already has several will not in my opinion clarify the situation, but will increase the confusion still further

A W SPENCE

PANCREATITIS AND MUMPS

SIR,—As a corollary to Mr Rodney Smith's interesting paper in your issue of Aug 22 on pancreatitis and diabetes, and in view of the fact that pancreatitis is one of the complications of mumps, it is perhaps relevant to mention the occasional association of diabetes and mumps Eight years ago I described in your columns (1934, i, 947) three cases of severe diabetes in children which came on within a few weeks of an attack of mumps and quoted five others which had been recorded In only three of these were there definite abdominal symptoms at the time of the attack of mumps Communications from other physicians have led me to suspect that the association is not as uncommon as is supposed and that it may not be fortuitous This is supported by E Gundersen's (*J infect Dis* 1927, 41, 197) observation that after epidemics of mumps there is a rise in the death-rate from severe diabetes in the young age-group

LESLIE COLE

Cambridge

multitude of committees—a prospect from which a joint consultative committee would save us

In industry one of the chief functions of the joint committees has been the attainment of maximum production, in hospitals the committees would aim at achieving the highest possible efficiency We are all alive to the tremendous demands which may soon be made on us The establishment of joint consultative committees would be the best way of discovering non-essential work and for making certain that every employee was on his toes fully conscious that he was a vital element in war service

SURGEON'S TOOLS THROUGH THE AGES

Sir Arthur Keith has remarked that a historical collection of surgical instruments is essential for an understanding of the history of surgery. Dr Thompson has had in his care the greatest collection of old and new surgical tools in Europe, including those used by Lister and a unique assemblage of gynæcological and obstetrical implements These numbered 2365 in 1925 and by 1941 had grown to about 3000 when an appalling disaster befell them A few of the instruments had been injured by water in a raid and the council of the British Institute of Surgical Technicians had undertaken the repair Before the work could be completed another raid destroyed nearly the whole of the surgical instrument museum Some 2000 were salvaged from the debris and of these 1554 specimens and a small collection of Chinese instruments were retrieved in fair condition The remainder, comprising most of the obstetric, Ismay, Heath, and Down Bros collections, were badly spoilt All the specimens, after careful examination and temporary refurbishing, were stored in waterproof metal cases given by the institute under whose direction, when happier days return, they will be renovated by the skilled craftsmen then available Meanwhile all who are interested in Dr Thompson's subject will benefit by his prescience in having provided them with a memento[1] of the collection as it was, lavishly illustrated in a way now only open to an American publisher He traces the scalpel from 3000 BC to the present time, the amputation knife from Susruta to Liston, and begins his history of the saw with a design made 5000 years ago He shows the trephine in its various stages from a piece of stone to its modern form His account of the vaginal speculum reveals the similarity of the modern specula with those of ancient Greek models, and notes that Sims's speculum was the first new basic design invented after many centuries of vaginal inspection The metal skull saw is shown as a comparatively modern tool, being attributed to surgeons of the Middle Ages The first bullet forceps is shown to date from 1562, corkscrew types of extractors having been used previously Other studies give the history of the tourniquet (the most modern of the surgical inventions described), trocars, phlebotomy instruments, and the operation table, of which a thirteenth century illustration (obviously drawn from life) is reproduced showing a patient on a laterally tilted model, lateral tilting is only a recent addition to our modern tables The first operation tables were used for the rehabilitation work of those early days It is to be hoped that Dr Thompson will expand his account while his memory of the collection belonging to the Royal College is still fresh

WAR-TIME MEDICAL EDUCATION IN CANADA

COURSES have been speeded up so that the second and subsequent years take only eight months and the ordinary rotating internship is cut down to eight months too This means that the present sixth-year group will graduate at Christmas instead of in the following fall, by which time the present fifth-year group will be finishing In this way a third (extra) batch is being turned out every two years It was a bit disconcerting at first, our correspondent writes April didn't carry with it the feeling of a new year and there was only one week's holiday between terms, students returning to find out their examination results were just in time for the next term But the speed up is proving effective without skimping training The chief difficulty has been financial, for the full fees are now needed at closer intervals with less opportunity to earn during holidays Most students expect to earn the year's fees and possibly their keep during the summer many prefer to be independent even though their parents are in a position to pay for them Now there are only two months' holiday in which to earn But the Government has sanctioned loans of $300 (£68) a year to students in their second, third and fourth years, while those in their fifth and sixth can join up and continue their studies on service pay at $1 30 (5s 10*d*) a day plus a subsistence allowance of $1 a day Graduates take internships under the same arrangement but without the subsistence allowance Much the same has happened in the States, where considerable thought has also been given to the choice between grants and loans On the whole, the feeling is against grants · a loan makes the student more aware of obligation to his university At all events, the arrangements seem to please prospective students, for the enrolment of freshmen is very great In Canada the official curriculum has been left unaltered except that in Alberta the anatomy and pharmacology courses have been simplified Many students however are getting more clinical work in their training by acting as junior interns during their last two years . This has helped to relieve the shortage of senior interns In the States it has been noticed that first and second year students know less of first-aid than does the trained layman and the subject is to be put immediately into the curriculum In the clinical courses emphasis is to be laid on tropical and war medicine

WAR AND THE DIFFICULT CHILD

PARENTS say with feeling that all children are difficult, but the children who stand out from their contemporaries in this respect just now are those who cannot fit into the social and emotional demands made upon them by a world at war it is, in fact, the situation rather than the child which is difficult Demands for some residential accommodation for such children many of whom are mentally subnormal though not actually defective, are increasing At the suggestion of the Board of Education, the Child Guidance Council have decided to open a home school[1] for boys sent by local authorities under section 80 of the Education Act, or committed to their care under the Children and Young Persons Act At present the council are seeking for a house to hold about 30 boys The Mental Health Emergency Committee are also facing this problem[2], in 1941 they published a memorandum pointing out the need for a classification of hostels, and for psychiatric supervision of difficult children The recommendations then made on classification, premises, staffing, play activities, rebilleting, and the special provisions needed by children requiring psychiatric treatment are being followed up in a growing number of areas, and plans are being made for children to receive psychiatric treatment either from psychiatrists visiting the hostels or at clinics in the neighbourhood Wherever psychiatric social workers are available they make any necessary plans for the rebilleting or supervision of such children Last January the committee conferred on the problems created in hostels by subnormal children who needed long and special training Representatives of the Ministry of Health and the Board of Education attended, and it was decided that in each region small hostels near schools able to cater for such children might be set aside for them Part of a generous gift from the British War Relief Society in the United States was used to provide extra play equipment for hostels, and some was set aside to equip a limited number of hostels where child guidance facilities were available Twenty applications from such hostels for sums ranging from £70 to £140 were met The evidence so far collected by the Emergency Committee confirms the earlier impression that the number of children—or of adults, too for that matter—showing nervous disorders as a result of terrifying incidents is relatively small, even among those who had previously been under treatment Cases due to changed circumstances arising out of the war though rather more

Obituary

JOHN MACPHERSON

KT, CB, MD EDIN, FRCPE

Sir John Macpherson, who died on Aug 14 at the age of 84, was a commissioner in lunacy for Scotland during the first twenty years of this century His wisdom and foresight was largely responsible for the initiation and framing of the Mental Deficiency and Lunacy (Scotland) Act in 1913, and it was thanks to his tactful dealing with men and matters that it was accomplished with so little friction He was born at Dores, near Inverness, the son of the Rev Allan Macpherson, and after graduating from the University of Edinburgh in 1882 he assisted Clouston at the Royal Edinburgh Asylum His quality was early appreciated, and in 1889 he was appointed superintendent of the Stirling District Asylum at Larbert Here the building and equipment of a modern hospital block and a pathological department gave him his opportunity as an administrator, and his appointment as lecturer in mental disease at the Edinburgh Royal Colleges also won him recognition as a teacher He was appointed commissioner in 1899, and of his work at the board a colleague writes

"Sir John was profoundly interested in the boarding-out of mental patients, which gives the patient a share in family life under kindly and understanding guardianship Although the supervision of these cases was the duty of his junior colleagues, he often found time to visit them I think he liked best of all to escape to his beloved Inverness, where many patients were placed in the homes of the kindly highland people in the crofts around, and for years after, on my visits to that district, patients, guardians and public officials alike would speak of him almost with reverence He had many calls on his time and did a good deal of public speaking, for he always attracted a large and appreciative audience He breathed a spirit of optimism as to the future of psychiatry and was a powerful advocate of early treatment It was an inspiration to accompany him on visits to mental hospitals, when the interests and wellbeing of the patients were always in his thoughts Behind Sir John's charm of personality there lay singleness of purpose, breadth of vision, balanced judgment and an outstanding intellect which was not confined to his own specialty"

Macpherson's retirement in 1921 proved to be another beginning, for a series of lectures which he delivered in Sydney the following year led to the founding of a chair of psychiatry at the university there of which he was persuaded to become the first occupant Five years later he returned to this country and finally settled at Cleeve in Somerset He leaves his widow, a sister of Sir David Wallace, FRCSE, with two daughters

DAVID LURIE

B M OXFD, F R C S, LIEUT-COLONEL SAMC

David Lurie was a brilliant student He took first place in all South Africa in the matriculation examination and graduated MA with distinction from Cape Town University He came to Oxford with a Rhodes scholarship and later won an entrance scholarship to Guy's where, perhaps because things came easily to him, he did not seem to take his clinical work too seriously Yet he qualified in the usual time and took his BM in 1926 After holding some surgical appointments he proceeded to the fellowship in 1932, and shortly afterwards returned to Johannesburg where he was appointed first registrar and later assistant surgeon at the General Hospital, and a teacher in the University of Witwatersrand He joined the South African Army Medical Corps last year and had lately opened a new hospital when he was killed in a motor accident in Egypt Though always quiet and reserved Lurie was a good companion, and he was a fine tennis and table-tennis player Through his death South Africa has lost one of her best surgeons

Colonel Tudor Germain Lavie, late RAMC (retd), who died on July 1 at the age of 80, was educated at Cheltenham College and St George's Hospital He took the Scottish and English conjoint examinations in 1884 and two years later received his commission as surgeon He served as surgeon-major during the South African war, taking part in the action at Karee Siding He was wounded early in the attack on Colonel Kekewich's column at Moedwell but he continued at his duties for many hours and was commended in dispatches He retired in 1919 with the rank of colonel Colonel Lavie married a sister of Major-General W H S Nickerson, VC, AMS

Notes and News

HOSPITAL JOINT CONSULTATIVE COMMITTEES

John R Griffith, AHOA

HOUSE GOVERNOR TO THE PRINCESS BEATRICE HOSPITAL

The principle of "consultations with the staff" has always been an accepted part of efficient hospital administration J E Stone,[1] for example, recommends monthly meetings of senior departmental officers as the best method of ensuring a regular interchange of views from all sections of the hospital staff, in voluntary hospitals the management looks to the medical staff for advice and suggestions on medical questions, and a special committee invariably exists for the purpose, a further extension of this idea is implicit in the recent recommendation of the British Hospitals Association that nurses' councils should be established to discuss and advise on nursing subjects Even where no machinery exists for periodical staff meetings, administrators often hold discussions with different members of the staff and it is generally realised that in the management of such a complex organism as a hospital much value is to be derived from drawing on the experience and knowledge of a wide variety of people

How often in wards and offices of hospitals can allusions be heard to the unsuitability of an item of equipment or the inadequacy of a new extension, which, in the view of the person speaking, could have been avoided if staff had been consulted prior to installation? Occasionally such complaints have little foundation but they are sometimes justified, permanent inconvenience and reduced efficiency has resulted in hospitals from plans completed without reference to the people who are to put them into practice Even the most humble member of the staff can make valuable suggestions for the improved working of the hospital or more economic running of his department if encouraged to do so War time needs have revealed how limited has been the application of this principle of consultations with the staff in the past Financial stress, staff shortage, fire watching and other special duties, dislocation of service in bombed hospitals and difficulties associated with rationing—these and many like problems might be solved more easily and effectively if hospital managements could obtain the cooperation of every member of the staff A somewhat similar position arose five or six months ago in industry and there the complexities of the situation were largely met by the setting-up of joint production committees These committees, consisting of representatives of the management and employees, meet and thrash out questions of production in ways which seem to be producing the goods Analogous joint committees in hospitals might bridge the gap which occasionally exists between management and staff, and generate suggestions for increased efficiency of hospital work

In every hospital a committee of this kind could be formed, consisting of representatives of the management (e g, the chairman of the hospital committee, the superintendent, the matron, and, in local authority hospitals, the steward) with members elected by the staff—medical, nursing (all grades), administrative, technical, maintenance and domestic Such a joint consultative committee would bring together the numerous hospital departments while making unnecessary the existence of several bodies representing different sections of the staff The recommendation of the BHA regarding nurses' councils will lead other groups of the staff to propose councils to advise on questions affecting their work, and if we are not careful we shall be overwhelmed by a when ampoules of the unneutralised S-methylisothiourea sulphate are opened, the odour is detectable in the atmosphere in a concentration of about 1 part in 10^{4} We were unable to detect the presence of mercaptans chemically Some ampoules were tested after six months and were apparently unaltered Because of its acidity this solution is irritant when injected subcutaneously, and up to the present we have only used it intravenously, or, in other investigations, by mouth We are now conducting observations with a solution adjusted to pH 6, with the object of discovering whether injections may be given intramuscularly

---

[1] Hospital Organisation and Management, London, 1939, p 292

Our practice of allowing the blood-pressure to fall before the administration of the pressor agent is obviously not to be employed as a routine, for when the blood-pressure has fallen there may be difficulty with intravenous injections if the veins become collapsed and empty In some cases this was obviated by arranging a slow intravenous drip at the beginning of the operation, and the additional control over the blood-pressure thus secured proved this a valuable feature in facilitating prompt injection

In a preliminary note[1] the trial of this substance in shock following injury has been advocated in cases where restoration of the blood-volume has not proved effective, or where circumstances are likely to delay such restoration We feel that the demonstration of its action in circulatory shock induced by spinal anæsthesia provides evidence that the substance is worthy of further trial in such cases But we would reiterate our view that it is not to be employed as a substitute for the restoration of diminished blood-volume when this is a practical procedure

SUMMARY

S-methylisothiourea sulphate raises the blood-pressure when this has been depressed by spinal anæsthesia

A further clinical trial of this substance appears warranted

We wish to thank Mr F Gordon Bell and Mr J A Jenkins, surgeons to the Dunedin Hospital, and Dr Marion Whyte and Dr J R Ritchie, anæsthetists, for their coöperation We are indebted to Prof E F D'Ath for his help in the preservation of sterile solutions of the substance

---

THE LOW-PRESSURE PHASE OF BLAST

A L LATNER M SC LOND, M B LPOOL, D I C, A R C S
LIEUTENANT RAMC, ASSISTANT LECTURER DEPARTMENT OF PHYSIOLOGY UNIVERSITY OF LIVERPOOL

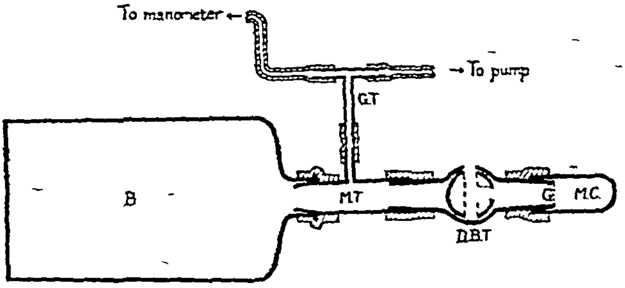
PREVIOUS investigators have attached much significance to the high-pressure component of the blast wave as the cause of blast lesions (Zuckerman 1940) The low-pressure phase has been somewhat neglected, and has not been regarded as a factor which can be primarily responsible for the production of lesions Zuckerman, however, has suggested that this phase may aggravate the injuries already produced by the high-pressure component The present experiments were carried out to determine the effects, if any, of exposure to low pressures of exceedingly short duration Mice were used as experimental animals

EXPERIMENTAL PROCEDURE AND FINDINGS

The apparatus used is illustrated in the figure The mouse was placed in the thick-walled glass mouse chamber, MC, which was then connected to the tap DBT by means of a thick rubber connexion The wide three-way bore of the tap was initially in the position indicated in the diagram by interrupted lines The mouse was therefore breathing room air Bottle B was evacuated as completely as possible by means of the 'Hi-vac' pump, which was kept running throughout the experiment Tap DBT was now rapidly turned through 90°, in a clockwise direction, and then just as rapidly returned to its original position This momentarily placed the small mouse chamber in communication with the large evacuated bottle and then returned it to its original connexion with room air The gauze G prevented the mouse from being sucked into the tap

Death occurred instantaneously or after a short interval in approximately half the animals exposed in this manner Post-mortem examination of the lungs always revealed hæmorrhagic areas, which were not as a rule symmetrically distributed Occasionally, other hæmorrhagic lesions, both intra- and extra-thoracic, were produced Such lesions have been found in the pericardium, thymus, liver, large intestine, pancreas and fallopian tubes They illustrate the fact that extrathoracic lesions produced by blast cannot be brought forward as evidence in favour of the high-pressure component being the injurious factor

The following three descriptions of fatalities give a more or less complete picture of the different types of fatal reaction observed



Experimental apparatus used B, Glass bottle of 8 litres capacity DBT metal tap (Douglas bag type) G, gauze protection, GT, glass T-piece, MC, glass mouse-chamber, MT, metal T-piece

ANIMAL 8—Death instantaneous *Autopsy* The lungs showed numerous hæmorrhagic areas, not symmetrical in their distribution, some of these areas appeared to be along the lines of ribs Blood stained froth was present in the trachea and bronchi There were a few small subserous hæmorrhages in the large intestine

ANIMAL 18—Death instantaneous *Autopsy* The typical lung lesions were present as well as hæmorrhages into the pericardium and thymus Extrathoracic hæmorrhages were also present in the liver, pancreas, pyloric region and large intestine The cæcum was greatly distended with blood The mesentery seemed abnormally congested

ANIMAL 9—Death after a few minutes, preceded by paralysis of the hind limbs, tachypnœa and orthopnœa, the appearance of blood stained froth at the mouth and nose, and finally convulsions *Autopsy* Patchy hæmorrhages in the lungs and blood stained froth in the trachea and bronchi Intercostal hæmorrhages were also present Small subserous hæmorrhages were seen in the pyloric stomach and a few in the large intestine

As in the case of true blast, the lung hæmorrhages, associated with instantaneous or rapid death, vary very much from animal to animal They tended to be greatest in those animals which survived for a short period In one case, in which death occurred after twenty minutes, the lungs were almost completely hepatised

Animals which recovered completely were killed with coal gas at varying intervals after exposure In this way the recovery process could be studied It was found to be more or less identical with previous descriptions, even to the occurrence of greyish patches in the midst of hæmorrhagic areas, described in human cases (Hadfield 1941) These areas showed pseudopneumonic mononuclear infiltration In sections stained with hæmatoxylin and eosin collapse of the alveoli rather clouded this picture The mononuclear infiltration was, however, beautifully demonstrated by using McGregor's azan-carmine stain (McGregor 1929) These animals which recovered often showed lesions which were unilateral or affected only one or two lobes This illustrates the danger of inferring that the occurrence of unilateral lesions, in animals exposed to the blast of explosions, indicates that blast lesions are necessarily produced by the high-pressure phase

DISCUSSION

Exposure to a rapidly produced low pressure of very short duration is thus capable of producing injuries similar to those produced by blast One may infer from this that the low-pressure phase of blast may possibly of the substance injected, an expression of caution in the administration of a new drug In most of the instances where the blood-pressure subsequently fell to any considerable degree this was the result of operative trauma, and further injections were necessary (fig 2) The response to the later injections was never as well-marked as that following the first injection, but some response was always obtained In a few cases, where severe operative procedures were in progress, intravenous saline or blood-transfusion was required at a later stage, but not before the pressure had first been elevated and maintained for a considerable period by S-methylisothiourea sulphate alone

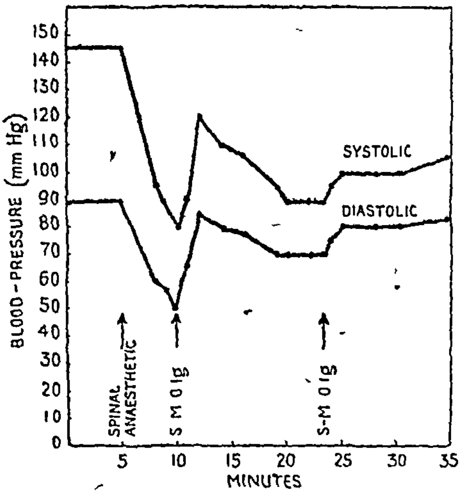


Fig 2—Response of blood pressure to repeated intra venous injections of 0 1 g of S-methylisothiourea

Although most of these cases received less than 0 25 g, it is possible in the absence of excessive slowing of the heart to give 0 5 g within a few hours, or 1 g in twelve hours, as was done in case 1, and in other unpublished cases of shock arising from different causes Experiments in animals suggest that still larger doses may be employed, but we have no experience of them in man, and in general it seems that when moderate doses fail to elevate the blood-pressure because of adverse circulatory conditions larger doses will be ineffective also Injection should always be made slowly, over a period of half to one minute, for an occasional patient has suffered slight distress when the substance has been given rapidly, but this has not occurred in the same patient when the injection was given slowly

DISCUSSION

This study was planned to determine the effect of S-methylisothiourea sulphate on the blood-pressure of patients under high spinal anæsthesia The technique employed was not the most satisfactory for routine use, since, *in order to demonstrate the effect of the substance*, the blood-pressure was allowed to fall before the injection was given The elaboration of a suitable technique was not, however, our immediate concern, but we can state that in every case in which S-methylisothiourea sulphate was employed the blood-pressure was raised (fig 3) In some instances it rose by as much as 65 mm Hg, and in 18 out of 20 cases it rose 20 mm or more It should be noted that as a rule the drug was given while the pressure was still falling, either as a result of the spinal anæsthetic or through handling of the abdominal viscera For this reason the rises in pressure recorded are certainly less than the full pharmacological effect which would have been registered had the full extent of the fall from spinal anæsthesia been attained before the pressor drug was given, or if the factor of operative trauma had been absent

It had previously been noted in animal experiments and in man (Nassif and Smirk, unpublished observations), that the rise in blood-pressure was often accompanied by slowing of the pulse, and slowing was noted in this series of cases This fall in heart-rate was usually slight, but in three cases there was a drop to about 50 beats per min, and in two to 40 beats Great slowing may set a limit to the amount of the drug which may be injected at any one time We intend to ascertain whether this slowing may be partly counteracted by atropine, thus permitting further administration of the substance

In view of the fact that substances such as ephedrine and lævo-α-hydroxy-β-methylamino-3-hydroxyethylbenzene hydrochloride ('Neosynephrine') are commonly employed in spinal anæsthesia, it was desirable to know if any incompatibility existed between these substances and S-methylisothiourea sulphate It has been demonstrated (Fastier and Smirk, unpublished observations) that the administration of S-methylisothiourea sulphate in the cat and dog renders these animals more sensitive to the pressor action of adrenaline On account of its practical and theoretical interest, therefore, *the effect of* S-methylisothiourea sulphate on the pressor action of other sympathomimetic amines was studied It was found that this substance and neosynephrine acted synergistically in respect of their pressor activities, and that a lesser degree of synergism also existed between it and ephedrine In a few instances our clinical observations suggest *the possibility that in man also the* combined effect of S-methylisothiourea sulphate with either neosynephrine or ephedrine is greater than the sum of their separate effects It seems, therefore, that this substance deserves further consideration as a pressor agent, to be held in reserve for use in cases where the administration of ephedrine or neosynephrine has given an inadequate response, and particularly if the synergism observed in animals and in our preliminary observations in man is confirmed So far as our observations go it appears that S-methylisothiourea sulphate would also deserve a trial as a routine pressor agent if the difficulties attendant on its intravenous administration were overcome

As our experience is limited to 20 cases, we cannot express any opinion as to its merits when compared with ephedrine or neosynephrine, and it must be fully recognised that the use of the drug is at present in an experimental stage Our limited clinical experience is unlikely to have brought us in contact with all its potential risks We have evidence from other work that it is unsuitable in congestive heart-failure, and we have, on theoretical grounds, avoided its use also in cases of coronary disease, hypertension and thyrotoxicosis Experiments in animals suggest that it is a safe substance, and experience in about 100 patients and normal subjects has not provided us as yet with any evidence against this, except in congestive heart-failure, where 2 patients experienced breathlessness of a few hours' duration after its use Quantities of as much as 0 8 g have been taken by mouth on several occasions by normal subjects (Nassif and Smirk, unpublished observations) without ill effect or the development of any symptoms

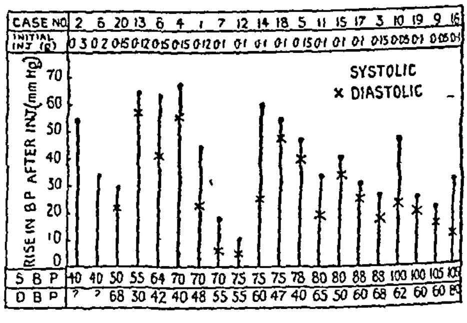

Fig 3—Synopsis of blood pressure responses to initial intra venous injection of S methylisothiourea

Since we do not intend to go further with the detailed study of *the technique in spinal anæsthesia*, we present for what they are worth a few preliminary ideas which may be of service to anyone who desires to make a practical trial of the substance S methylisothiourea sulphate is a relatively simple substance, which may be prepared readily in the laboratory and can be purchased commercially[3] We do not know anything concerning *the purity of commercial samples* We have employed the substance in a 10% aqueous solution placed in ampoules of 2 ml, each, which were sterilised by tyndallisation This solution is definitely acid and apparently does not decompose to any appreciable extent If, however, the solution is rendered alkaline it begins to decompose at a pH of about 9, liberating the powerfully smelling substance methyl mercaptan An odour somewhat similar to that of methyl mercaptan is noticed when ampoules of the unneutralised S-methylisothiourea sulphate are opened, the odour is detectable in the atmosphere in a concentration of about 1 part in 10^{14} We were unable to detect the presence of mercaptans chemically Some ampoules were tested after six months and were apparently unaltered Because of its acidity this solution is irritant when injected subcutaneously, and up to the present we have only used it intravenously, or, in other investigations, by mouth We are now conducting observations with a solution adjusted to pH 6, with the object of discovering whether injections may be given intramuscularly

---

[3] It can be obtained in Great Britain from Messrs British Drug Houses

Our practice of allowing the blood-pressure to fall before the administration of the pressor agent is obviously not to be employed as a routine, for when the blood-pressure has fallen there may be difficulty with intravenous injections if the veins become collapsed and empty In some cases this was obviated by arranging a slow intravenous drip at the beginning of the operation, and the additional control over the blood-pressure thus secured proved this a valuable feature in facilitating prompt injection

In a preliminary note[1] the trial of this substance in shock following injury has been advocated in cases where restoration of the blood-volume has not proved effective, or where circumstances are likely to delay such restoration We feel that the demonstration of its action in circulatory shock induced by spinal anæsthesia provides evidence that the substance is worthy of further trial in such cases But we would reiterate our view that it is not to be employed as a substitute for the restoration of diminished blood-volume when this is a practical procedure

SUMMARY

S-methylisothiourea sulphate raises the blood-pressure when this has been depressed by spinal anæsthesia

A further clinical trial of this substance appears warranted

We wish to thank Mr F Gordon Bell and Mr J A Jenkins, surgeons to the Dunedin Hospital, and Dr Marion Whyte and Dr J R Ritchie, anæsthetists, for their cooperation We are indebted to Prof E F D'Ath for his help in the preservation of sterile solutions of the substance

---

THE LOW-PRESSURE PHASE OF BLAST

A L LATNER, M SC LOND, M B LPOOL, D I C, A R C S
LIEUTENANT RAMC, ASSISTANT LECTURER, DEPARTMENT OF PHYSIOLOGY UNIVERSITY OF LIVERPOOL

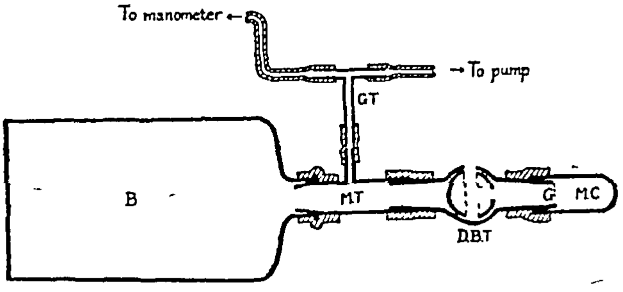
PREVIOUS investigators have attached much significance to the high-pressure component of the blast wave as the cause of blast lesions (Zuckerman 1940) The low-pressure phase has been somewhat neglected, and has not been regarded as a factor which can be primarily responsible for the production of lesions Zuckerman, however, has suggested that this phase may aggravate the injuries already produced by the high-pressure component The present experiments were carried out to determine the effects, if any, of exposure to low pressures of exceedingly short duration Mice were used as experimental animals

EXPERIMENTAL PROCEDURE AND FINDINGS

The apparatus used is illustrated in the figure The mouse was placed in the thick-walled glass mouse chamber, MC, which was then connected to the tap DBT by means of a thick rubber connexion The wide three-way bore of the tap was initially in the position indicated in the diagram by interrupted lines The mouse was therefore breathing room air Bottle B was evacuated as completely as possible by means of the 'Hi-vac' pump, which was kept running throughout the experiment Tap DBT was now rapidly turned through 90°, in a clockwise direction, and then just as rapidly returned to its original position This momentarily placed the small mouse chamber in communication with the large evacuated bottle and then returned it to its original connexion with room air The gauze G prevented the mouse from being sucked into the tap

Death occurred instantaneously, or after a short interval, in approximately half the animals exposed in this manner Post-mortem examination of the lungs always revealed hæmorrhagic areas, which were not as a rule symmetrically distributed Occasionally, other hæmorrhagic lesions, both intra- and extra-thoracic, were produced Such lesions have been found in the pericardium, thymus, liver, large intestine, pancreas and fallopian tubes They illustrate the fact that extrathoracic lesions produced by blast cannot be brought forward as evidence in favour of the high-pressure component being the injurious factor

The following three descriptions of fatalities give a more or less complete picture of the different types of fatal reaction observed



Experimental apparatus used B, Glass bottle of 8 litres capacity DBT metal tap (Douglas bag type) G, gauze protection, GT, glass T-piece, MC, glass mouse-chamber, MT, metal T piece

ANIMAL 8—Death instantaneous *Autopsy* The lungs showed numerous hæmorrhagic areas, not symmetrical in their distribution, some of these areas appeared to be along the lines of ribs Blood stained froth was present in the trachea and bronchi There were a few small subserous hæmorrhages in the large intestine

ANIMAL 18—Death instantaneous *Autopsy* The typical lung lesions were present as well as hæmorrhages into the pericardium and thymus Extrathoracic hæmorrhages were also present in the liver, pancreas, pyloric region and large intestine The cæcum was greatly distended with blood The mesentery seemed abnormally congested

ANIMAL 9—Death after a few minutes, preceded by paralysis of the hind limbs, tachypnœa and orthopnœa, the appearance of blood stained froth at the mouth and nose, and finally convulsions *Autopsy* Patchy hæmorrhages in the lungs and blood stained froth in the trachea and bronchi Intercostal hæmorrhages were also present Small subserous hæmorrhages were seen in the pyloric stomach and a few in the large intestine

As in the case of true blast, the lung hæmorrhages, associated with instantaneous or rapid death, vary very much from animal to animal They tended to be greatest in those animals which survived for a short period In one case, in which death occurred after twenty minutes, the lungs were almost completely hepatised

Animals which recovered completely were killed with coal gas at varying intervals after exposure In this way the recovery process could be studied It was found to be more or less identical with previous descriptions, even to the occurrence of greyish patches in the midst of hæmorrhagic areas, described in human cases (Hadfield 1941) These areas showed pseudopneumonic mononuclear infiltration In sections stained with hæmatoxylin and eosin collapse of the alveoli rather clouded this picture The mononuclear infiltration was, however, beautifully demonstrated by using McGregor's azan-carmine stain (McGregor 1929) These animals which recovered often showed lesions which were unilateral or affected only one or two lobes This illustrates the danger of inferring that the occurrence of unilateral lesions, in animals exposed to the blast of explosions, indicates that blast lesions are necessarily produced by the high-pressure phase

DISCUSSION

Exposure to a rapidly produced low pressure of very short duration is thus capable of producing injuries similar to those produced by blast One may infer from this that the low-pressure phase of blast may possibly have an importance greater than that previously attributed to it It may be argued that the period of exposure to low pressures in these experiments has been greater than in true blast In order to overcome this criticism an apparatus has been devised in which mice can be exposed to known pressures, high or low, for measurable periods corresponding to those of blast Nevertheless, it is felt that even with the present apparatus the period of exposure to low pressures is exceedingly short and probably of the same order as that of blast

What is the mechanism whereby this short exposure to low pressure produces lesions ? In this communication the lung lesions only will be considered Blast injuries of the lungs bear some resemblance to the injuries that occasionally occur with the Davis escape apparatus The submarine fatalities are known to be caused by over-inflation due to the fact that the pressure of air in the lungs is greater than that of the surrounding atmosphere In the case of blast such a pressure difference might be achieved in two ways One possibility is that the lungs are over-inflated by the high-pressure component passing directly down the bronchial tree That this does not occur is adequately demonstrated by the findings of Zuckerman and his co-workers (1942) The second possibility is rather more subtle It depends on the assumption that the pressure changes of blast are not directly communicated to the inside of the lung This is borne out by the relative narrowness of the trachea and the exceedingly short duration of the blast wave If this state of affairs holds good, then the intrapulmonary pressure would be greater than the outside pressure during the low-pressure phase of blast The large area of body surface would make this pressure difference very effective The resulting over-inflation of the lungs would tear some of the pulmonary capillaries and so produce the hæmorrhagic lesions, hence the lesions of the experiments just described

The lung bleeding of blast injuries continues for quite long periods This can be explained by a similar mechanism of tearing of the capillaries In this case, not by pressure differences but by the lung movements causing a pull on the fibrin strands produced by coagulation and early organisation This suggestion obviously has an important bearing on treatment One might suggest immobilising the chest with bandage as well as the inhalation of pure oxygen

It seems possible that the lung lesions of blast are primarily due to over-stretching of the lung substance (1) during the low-pressure phase, by the mechanism already indicated, and (2) at the end of the high-pressure phase, by the elastic recoil of the thoracic wall occurring after compression These factors would tend to be additive As far as can be ascertained from published work this suggestion has not previously been made It would indicate a method of preventing blast injuries of the lung Over-inflation should not occur if the chest is covered with a tight inelastic bandage or jacket

SUMMARY

Mice have been exposed to sudden low pressures of short duration

Approximately half the animals died instantly or within a short period

Typical blast lesions were produced, both intra- and extra-thoracic

In the treatment of blast injuries of the lung immobilisation of the chest with a bandage might prevent further bleeding into the lung

Covering the chest with a tight bandage or jacket should help to prevent blast injury by checking over-stretching of the lung substance

I wish to thank Prof H E Roaf, in whose department this work is being carried out, as well as Prof T B Davie and Dr C V Harrison, of the department of pathology, for criticism and advice

REACTION OF THE BLOOD LYMPHOCYTES TO TRAUMA AND HEALING

ALAN H CRUICKSHANK, MD ABERD
ASSISTANT IN PATHOLOGY IN THE UNIVERSITY OF ABERDEEN

IT was recorded by Erf (1940) that when the stomach, intestines, spleen, pancreas and mesenteric lymph nodes were removed from rabbits a severe and persistent lymphopenia developed within 2 hours of the operation and was not relieved by the administration of lymphocytes intravenously After the operation the rabbits recovered from the anæsthetic and were able to hop about, they lived from 8 to 24 hours These experiments were carried out to test the suggestion by Bunting and Huston (1921) that lymphocytes escaped from the circulation by migrating through the mucous membrane of the alimentary canal Erf's results did not support the idea that such migration took place, though it has since been confirmed (Sanders, Florey and Barnes 1940) that very large numbers of lymphocytes must disappear from the circulation daily On the contrary Erf's results suggest that the gut, spleen and mesenteric nodes are the main source of the blood lymphocytes

Yoffey (1942), also testing the suggestion of Bunting and Huston, removed the greater part of the small and large intestines in 15 dogs Within 2–3 hours there was no constant change in the blood lymphocytes Of the 15 dogs, 6 showed a fall in their lymphocytes, 6 a rise and 3 no change There was always a considerable increase in the polymorphonuclears, and the red cells showed little change Sanders, Florey and Barnes (1940) noted that the blood picture was considerably altered by operations other than removal of the gut They gave the following figures for the changes in the blood lymphocytes produced by drastic operative procedures on cats

Operation	*Lymphos per c mm of blood* *Before op*	*6 hr later*
Decerebration with exposure of colon	7200 6600	810 1100
Decapitation and collection of intestinal secretions	5100 6300	2200 4800

The following experiments were carried out on albino rats, using the counting methods described elsewhere (Cruickshank 1941)

Removal of the stomach, small intestine, colon, mesenteric lymph-nodes and spleen —The operation was performed under 'Nembutal' and ether, after it the rat was always kept quiet with nembutal until it died Effects on the blood lymphocytes are shown in table I (rats 1–5) All showed a considerable fall in their blood lymphocytes There were no notable changes in the red cell counts The results of removing parts of the alimentary canal are shown in the same table (rats 6–12) All these animals showed a diminution of lymphocytes at some stage of the experiment It will be noted that in some, towards the end of the experiment, there was a tendency for the lymphocytes to rise again This was conspicuous in rat 10 where there was only a slight fall followed by a fairly decided rise

It was usually found that the fall of the lymphocytes was gradual and reached a maximum in about 24 hours Immediately after the operation there was little change in the lymphocytes as can be seen from the two following experimental operations

Rat A
Immediately before gastrectomy, 8064 lymphocytes per c mm
" after " 8171 " " "

Rat B
Immediately before gastrectomy 8102 lymphocytes per c mm
" after " 8060 " " "

Anæsthesia alone caused no fall

Operations unconnected with the alimentary canal —All the experiments so far had had some connexion with the alimentary canal (even those of Sanders, Florey and Barnes) The results obtained after decerebration in rat 13 and after wounds of the skin (made by the method of Young, Fisher and Young 1941) in rabbits 1, 2 and 3 are shown in table I In rabbit 3 the lymphocytes were found to be higher the day after the operation than they had been originally, but in all the other experiments there was a fall

Human observations —Patients who underwent various operations were then investigated and the effects of their operations on their blood lymphocytes are shown in table II Of the 27 cases, 22 showed some fall in the blood lymphocytes The fall was greatest after severe operations in patients who had had a lymphocytosis before operation Of the 5 which showed an increase in the lymphocytes the operation involved little trauma in cases 23, 24 and 25 In case 26 a transfusion of several pints of blood had been given In case 27 the amputation of the leg was carried out because of gangrene from thrombosis in an arteriosclerotic artery, and the low level of the lymphocytes before the operation suggests that the onset of the gangrene had had an effect similar to that of an operation involving trauma to tissue

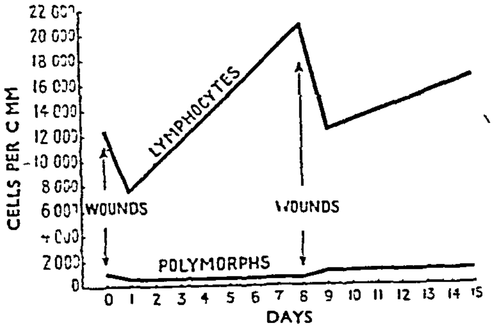

Fig 1—Effect on leucocyte count of second skin wounds in a rat during healing of the first The polymorphs were unusually few in this animal, but the lymphocytes show a well marked response to the wounds

Animal experiments with recovery —As stated, in some of the animals which lived for 24 hours or more the lymphocytes showed a tendency to rise towards the end of the experiment (e g, rat 10) In animals which had received wounds, and where the wounds were allowed to heal, a decided lymphocytosis followed the initial fall The average figures in 6 rabbits were ·

	Before operation	*After operation* 1 *day*	*After operation* 10 *days*
Lymphocytes	5350	3683	8767
Polymorphs	3950	3333	5850

And in 6 rats.

	Before operation	*After* 1 *day*	*After operation* 7 *days*	*After operation* 12 *days*
Lymphocytes	7567	5667	12 050	12 817
Polymorphs	2983	1067	3583	2200

The effect of a second series of skin wounds inflicted during the healing of primary wounds in a rat is shown in fig 1

Effects of infection —No such lymphocytosis was noted when 5 rats which had been injected subcutaneously with staphylococci in doses sufficient to produce abscesses had blood-counts done at corresponding times In these animals the lymphocytes fell after the injection and remained somewhat below the original level as the abscess ran its course

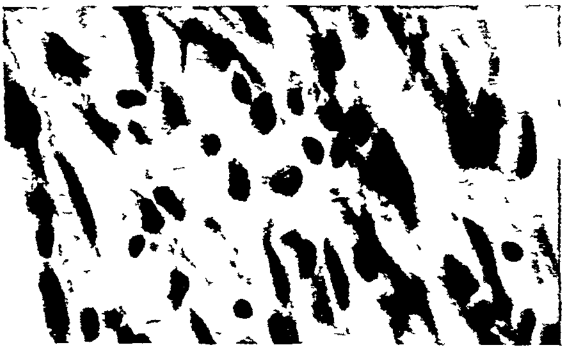

Fig 2.—Cells indistinguishable from lymphocytes among fibroblasts in healing wounds

	Before injection	*After injection* 1 *day*	*After injection* 4 *days*	*After injection* 10 *days*
Lymphocytes	7780	6920	5540	5425
Polymorphs	2460	4380	2740	2425

DISCUSSION

From the results of these experiments it seems that the effect of an operation inflicting much trauma or loss of tissue is to cause a fall in the blood lymphocytes When healing is taking place the blood shows a lymphocytosis These findings suggest that the lymphocyte plays an important part in healing and support the view that it can undergo transformation into other types of cell It is suggested that when tissue has been removed lymphocytes accumulate in the region of the loss, in the course of the first 24 hours, and as a result the blood lymphocytes fall The need for lymphocytes is met by increased output from the lymphatic tissue and a lymphocytosis in the blood follows This suggestion receives some support from the presence of considerable numbers of cells, histologically indistinguishable from lymphocytes, among the fibroblasts of the healing wounds (fig 2), and Maximow (1928) claims to have observed the transformation of lymphocytes into fibroblasts in tissue culture

SUMMARY

After severe operations in animals (e g , removal of the whole or part of the alimentary canal, decerebration, wounds of skin) the blood lymphocytes were found to fall within a few hours

In 27 human subjects lymphocyte counts were done before, and 24 hours after, various operations , 22 showed a fall in their blood lymphocytes after the operation

In rabbits and rats there was found to be a blood lymphocytosis during the healing of wounds of the skin

These findings seem to support the view that lymphocytes may undergo transformation into other types of cell —for example, into fibroblasts

BLOOD-TRANSFUSION NEEDLE

H F Green, MB CAMB, DPH
AREA MEDICAL OFFICER OF HEALTH LEOMINSTER

At the inception of the local transfusion services, the need for an adequate supply of sharpened needles became apparent We had to sharpen our own needles and for this purpose a small arkansas stone with a rounded top roughly fitting the bevel of the needle was used It was found with some needles that the point could easily be introduced into the vein, while others would either stick when going through the skin or " buttonhole " the vein A search was made in the published work for guidance as to the shape and size of the bevel of the needle

Riddell [1] states that " The end of the needle should not be too pointed or it will tear or perforate the posterior wall of the vein In other words, the bevel should be short though it should have well-cared-for cutting edges It is of no consequence whether the bevel faces upwards or downwards as long as it is sharp " French [2] in 1912 described the use of a hollow needle of large bore for the removal of blood , he gives the length as 2–4 cm and diameter as 2 mm , but does not make any comment on the point In 1927 [3] he illustrated what has since been called French's needle and states that by sharpening the back he produces a triangular point which will enter the skin more easily His illustration shows a needle with a flat bevel 8 mm long A needle with a flat bevel seems to have the disadvantage of occupying too great a volume inside the vein and thus of slowing the flow of blood

ESSENTIALS OF THE POINT AND BEVEL

This investigation was undertaken with the idea of standardising the specification of the bevel of a transfusion needle so that each point could be assessed separately Examination of new needles with a magnifying glass (× 10) showed that they were for the most part very rough in their finish and quite a few were blunt It is unwise to assume a new needle to be fit for use A set of small emery grindstones were fitted to a dentist's mandrel The mandrel was held in a special chuck and the whole was driven by means of a Singer sewing machine electric motor, controlled by foot Experience showed that the grindstone should have a diameter of between 18 and 22 mm Two stones were used, one coarse and one fine A hard rubber buff was used for polishing the bevel and removing the feathered edges By using hard rubber instead of soft rubber with emery compound it was possible to avoid finishing off by hand on an oil stone

By a tedious process of trial and error the following facts were established

1 If the bevel is too short, or represents the arc of too small a circle, there is difficulty in pushing the needle through the skin and the consequent jerk is liable to buttonhole the vein For a needle with an external diameter of 2 mm , the bevel should represent an arc of a circle of 19–22 mm The tangent of this circle at the point of the needle should be parallel to the back of the needle If the bevel is too short the vein may be split and quite a large hæmatoma formed

2 If the shoulder of the needle is not rounded off the needle again tends to go through the skin with a jerk

3 The point must be sharp otherwise it fails to engage the wall of the vein and produces clumsiness in technique

4 The cutting edge at the sides of the needle must extend up the side of the bevel just so far as is necessary to make the cut in the skin large enough to admit the needle Failure to sharpen the cutting edge causes the needle to stick first in the skin and then in the vein wall Thus, though a needle may look perfect to the naked eye and have a very sharp point it may in fact be practically impossible to make it cut through the skin The cutting edge must be undercut just sufficient for sharpness but not so much that it is difficult to make a smooth yet keen edge The sharpness of this edge is one of the most important features of a needle , it ensures a clean cut into the skin, without tearing or stretching of the skin and vein wall Other things being equal this factor bears directly on the rate of healing

5 The aperture in the bevel should have rounded edges The existence of sharp serrations which can catch in either the skin or the vein wall is one of the most potent sources of trouble in venepuncture

If all these considerations are attended to extremely little pressure will be needed for introducing the needle into the vein , with such a needle extremely few people will be found to have veins from which blood cannot be obtained without the use of suction

For whatever purpose a needle may be used—intradermal work, anæsthesia of the periosteum for sternal puncture, simple hypodermic inoculation or the like—there is an optimal shape for the bevel and point which can be worked out A standard specification for the point and bevel of any needle would be a great advantage both to the doctor and the manufacturer and the following form is suggested

1 *Specification of Steel Tubing Used*

2 *Diameter of the Bevel* —This term would refer to the diameter of the circle of which the bevel forms an arc

3 *Angle of the Bevel* —The angle between the tangent of the bevel at the point of the needle and the line of the back of the needle, representing the back of the needle

4 *Angle of the Point* —The angle made by the two sides of the bevel where they meet to form the point of the needle

5 *Shoulder* —It should be stated whether or not the shoulder is to be rounded off

On this scheme here is a specification for a taking needle steel tubing 2 mm diameter , bevel diameter 22 mm , angle of bevel 0° , angle of point 40° , shoulder rounded off And here is one for an intradermal needle steel tubing 27 s w g , bevel diameter 10 mm , angle of bevel 35° , angle of point 60° , shoulder not rounded off (the shoulder is left in this case in order that the needle may be impeded in its passage through the skin)

THE BORE

Examination of needles under the magnifying glass shows the almost incredible roughness of the bore, and steel-tube manufacturers say that this roughness cannot be avoided It is impossible to clean all the blood and dirt from the crevices in the inner wall of a standard needle Accordingly, needles were polished by spinning them at high speed and introducing a steel knitting needle (size 17) through the bore, covering the knitting-needle first with a coarse valve-grinding paste, then with a fine grinding paste (polishing paste), and finally with either ' Diamantine ' or chromium sesquioxide suspended in spirit The needle was cleaned out with

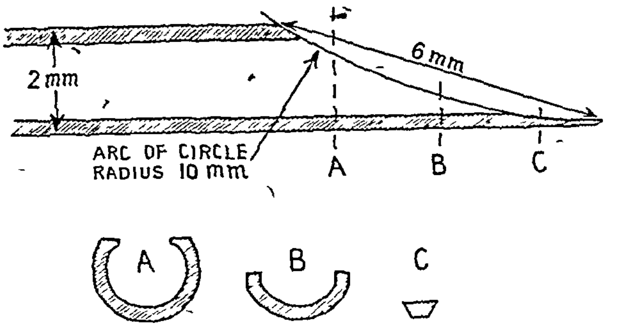
[3] *Proc R Soc Med* 1927, 20, 1558



Above longitudinal section through needle showing the arc of circle making the bevel whose angle is 0°
Below cross sections of needle showing the formation of cutting edges

darning wool and trichlorethylene or acetone between each of these operations The rate of flow of blood through a needle treated in this way appeared to be increased by about 25% At the same time the tendency to clot was greatly diminished and it was noticeable that blood usually flowed just as quickly at the end of the operation as at the beginning Once the bore is polished cleaning becomes much simpler, and the occasional use of diamantine or *chromium sesquioxide will maintain a* first-rate finish

METHOD OF GRINDING NEEDLES

Two circular stones, each mounted on its own mandrel (diameter 22 mm), one medium or medium fine and the other coarse grit , personally, I use a " green emery " wheel

A hard rubber buff or other finishing buff. Here I use a very hard rubber impregnated with graphite This wheel must also be of 22 mm diameter and mounted on its own mandrel

A riffler This is a small cutting tool not unlike a file, cone shaped and mounted on a shaft of the same size as the mandrel carrying the grinding stones

A small polishing lathe driven by an electric motor, preferably of ¼ horse-power *This motor must be foot controlled* and capable of large variations in speed The polishing lathe consists of a spindle mounted on bearings with a driving belt at one end or in the centre and a small chuck attached to the spindle which will grip the mandrels or the riffler If this spindle and chuck is hollow right through it can be used for holding the needle and polishing its bore as well Great care must be taken under these circumstances that flying grit does not get into the bearings

Both grindstones and polishing wheels must be trued up before use This is best done with an industrial diamond mounted for the purpose, but can be satisfactorily done with the edge of an ordinary wheel glass-cutter The grinding wheel is spun at its maximum speed The diamond or glass cutter is thus passed gently backwards and forwards across the wheel until all irregularities have been removed and the wheel is dead centre However lightly a needle is allowed to rest against the wheel it should never bounce or chatter even when the wheel is at maximum speed

Unless a complete new bevel is to be made it is not necessary to use the coarse grinding wheel The needle is placed against the stone so that the bevel fits roughly against the circumference of the stone The motor is then started at first very slowly and then accelerated up to about 8000–10,000 revolutions per minute This will produce an excessive amount of heat which must be dissipated by a continuous drip of water on the stone Where the angle of the bevel is too great and it is therefore desired to move the bevel up the shaft of the needle a slight pressure in an upward direction will do this When the point is too thick the pressure must not be upwards but forwards By a combination of pressures upwards and forwards it is not difficult to set any bevel Once set, the edges must be brought together to a point by using the side of the stone and moving the needle in a combined twisting and circular movement so as to produce a cutting edge as shown in the figure It is best to put the rounded shoulder on to the needle after the point has been made At this stage a lot of sharp and " scaggy " bits of metal will be found attached to the inner border of the aperture The riffler is then put in the chuck, and, using a speed of 8000–10,000 r p m , it cuts away these adventitia, leaving a smooth edge to the aperture which will not catch on the skin The finishing-off process is carried out in exactly the same way as the grinding process A hard rubber buff is used dry

The needle must not be allowed to overheat at all during the grinding process Overheating is shown by discoloration of the metal A cutting edge and point made of overheated steel never last long Care must be taken in the removal of grit and particles of steel from the inside of the needle after it has been sharpened

PERNICIOUS ANÆMIA AND PITUITARY INSUFFICIENCY

L J WITTS, MD MANC, DM OXFD, FRCP
NUFFIELD PROFESSOR OF CLINICAL MEDICINE AT THE RADCLIFFE INFIRMARY OXFORD

IN 1937 Snapper, Groen, Hunter and I[1] reported a series of cases in which pituitary disease was associated with achlorhydria and anæmia, usually of the Addisonian type Since then I have had two more cases under observation and I have learnt of others from colleagues, so that I have little doubt that the association of these rare diseases is more than a coincidence A brief account of the two cases follows The first was not absolutely proved to be an Addisonian anæmia as no evidence of megaloblastic degeneration of the bone-marrow was secured on sternal puncture, but about the second there can be hardly any doubt

CASE 1 —Male, aged 58 The salient features in his past history were that only one testis had descended, that he had not married till age 46 and the union was sterile The first symptoms of real illness were not till age 56 when he developed bitemporal hemianopia and pernicious anæmia He showed in full measure the artistic ability, the gentleness and the dependence which so often characterise the personality structure of hypopituitarism His skin was lemon yellow and smooth, and his scalp hair thin and silky Stereoscopic radiograms showed an enormous pituitary fossa with an intrasellar fleck of calcification, and Mr J Pennybacker diagnosed a cranio pharyngioma There was achlorhydria and anæmia of high colour index with a Price Jones curve at the extreme right of the normal range The basal metabolic rate was normal In spite of treatment with liver the red cell count at first fell and reached its lowest level—red cells 2,730,000 per c mm , hæmoglobin 66%, colour index 1 2, white cells 6000 per c mm , differential count normal Although a successful sternal puncture was made at this time, the smears were identical with the peripheral blood A large internal hæmorrhoid, from which there had been streaky bleeding, was treated by the injection of phenol in oil , thereafter the patient responded well to liver and his count rapidly improved to 4,230,000 red cells per c mm and 96% of hæmoglobin

CASE 2 —Female, aged 44 She was a small wizened woman with an almost simian appearance and looked much older than her age, although her hair was still black She had never menstruated The genitalia were small and underdeveloped, and the breasts and nipples small and prepuberal The basal metabolic rate was within normal limits There were no gross changes in the visual fields or skull though the pituitary fossa was small The excretion of 17 ketosteroids was less than 3 mg a day (C L Cope) The endocrine lesion was diagnosed as atrophy or hypofunction of the anterior lobe of the pituitary gland The complaint which had brought her to hospital was a severe anæmia of the Addisonian type—red cells 1,710,000 per c mm , hæmoglobin 38%, colour index 1 1, white cells 9000 per c mm , differential count normal, serum bilirubin 2 4 mg per 100 c cm , achlorhydria On treatment with liver she had a classical reticulocyte crisis and her hæmoglobin rose rapidly to 80%

The association of pernicious anæmia with hyperthyroidism,[2] with pregnancy and with pituitary disease, suggests that there is a hormonal element or mechanism which can lead to the degeneration of the cells which secrete the intrinsic factor The incidence of pernicious anæmia increases with advancing years, and from a wider biological point of view we may consider the association of pernicious anæmia with hypopituitarism as another example of the precocious senile changes to which the patient with pituitary disease is liable From the more immediately practical point of view it is useful to remember that some of the physical and nervous symptoms of pituitary disease may be due in rare instances to an associated pernicious anæmia and may be relieved by treatment with liver

SULPHAMETHAZINE

CLINICAL TRIALS IN CHILDREN

P A JENNINGS
MB NUI, DPH
DEPUTY MEDICAL SUPERINTENDENT

W H PATTERSON
MD BELF, DCH
MEDICAL SUPERINTENDENT

BOOTH HALL CHILDREN'S HOSPITAL, MANCHESTER

OUR colleagues, Macartney and others,[1] recently used sulphamethazine in the treatment of 73 cases of lobar pneumonia in adults and reported on its high therapeutic efficiency, the low incidence of nausea and vomiting compared with sulphapyridine, and the absence of cyanosis They considered renal complications unlikely in view of the relatively high solubility of the compound

This paper deals with the use of sulphamethazine in children and infants, 32 acutely ill and 6 healthy

DOSAGE, BLOOD CONCENTRATION AND TOLERANCE

The doses given by mouth were

Age (yr)	Initial dose (g)	Six hourly dose (g)
0–½	1 0	0 5
½–2	1 5	0 75
2–5	2 0	1 0
5–10	2 5	1 5
10–15	3 0	2 0

For patients under 5 years the drug is best dispensed in powders for accuracy, and can be given in suspension in milk or fruit juice The sodium salt of sulphamethazine for intramuscular or intravenous injection was supplied in ampoules of 3 c cm , each containing 1 g to be diluted to 10 c cm with sterile distilled water before use The dose of this given was 0 05 g per pound body-weight The precaution was taken of never adding a dose of the sodium salt to transfusion fluids such as saline, glucose or blood There was only one occasion to use the intravenous route, but the intramuscular route was used a number of times and in no case was there any ill effect at the site of injection

The level of the free drug in the blood was estimated in the first 24 hours of treatment and daily thereafter No attempt was made to keep the level within preconceived limits , 184 blood-level estimations were made—138 on 32 sick children and 46 on 6 healthy children The level in the cerebrospinal fluid was measured on 17 occasions The children in the "ill" group ranged in age from 2½ months to 13 years, and in these the average amount of sulphamethazine given in the first 24 hours was 4 2 g , giving a mean blood concentration of 16 5 mg per 100 c cm The lowest concentration was 3 8 mg and the highest 29 8 mg per 100 c cm The highest figure was obtained in an infant aged 2½ months, and it was found that on the standard dosage the highest levels were obtained in children under 3 years This is the age-group with the highest fatality in both bronchopneumonia and meningococcal meningitis and the early attainment of high levels is a sound principle [2] In all the ill patients the highest blood-level attained by each case throughout treatment was reached within 48 hours of the beginning of the therapy and in many cases within 24 hours Thereafter the level tended to drop considerably The average duration of chemotherapy was 4½ days , it was either discontinued abruptly or reduced doses were given for 24 hours and it was then stopped Estimations made the day after discontinuance gave only a trace or a very low concentration of the drug In 6 healthy children between the ages of 1 year and 12 years the standard dose for their age was given for 7 days and the drug level was estimated daily There was considerable individual variation The lowest figure obtained was 3 mg and the highest 22 4 mg per 100 c cm There was a notable absence of the drop in level which took place in the sick child as he improved clinically

Sulphamethazine was well tolerated by all age-groups Vomiting attributable to the drug did not occur in any of the sick children Nausea and depression are not easy to assess in children and are not notable with other sulphonamides, but it has been estimated that about a third of child patients having sulphapyridine therapy vomit as a direct result, particularly in the intermediate stages of treatment There was no cyanosis and no sign of renal trouble White-cell counts made on a number of cases during and after stopping treatment showed no evidence of depression of leucopoietic activity One infant of 5 months who had a total quantity of 7 g sulphamethazine with a maximum blood-level of 13 8 mg per 100 c cm developed a morbilliform rash Two of the healthy children aged 1 year and 10 years developed rashes after having 23 g and 53 g respectively , there was no other detectable constitutional disturbance These amounts are much greater than those required for ill children of the same age-groups

CLINICAL NOTES

Bronchopneumonia —The drug was given to 11 children with bronchopneumonia, of whom 9 were under 2 years The cases were selected because of clinical severity The diagnosis was confirmed by two observers and in all but 2 cases was supported by radiographic evidence All patients responded within 36 hours of the start of treatment and all recovered One child had a relapse a week after treatment was stopped , no chemotherapy was given for 4 days and then sulphamethazine was restarted with satisfactory response

Meningococcal meningitis —Ten patients aged 2 months to 10 years suffering from meningococcal meningitis were given sulphamethazine Group I meningococcus was isolated from 8 cases and 7 of these recovered The fatal case was in an infant of 2 months admitted to hospital on the 5th day of disease, he died 18 hours after admission having had a total dosage of 2 g

Group II meningococcus was isolated from one patient This infant, aged 8 months, died after 3½ days in hospital During this time he had 9 75 g of sulphamethazine The level of the free drug in the blood on the first day of treatment was 8 8 mg per 100 c cm , and it was 15 mg on the second day There was no evidence of improvement after increase of the standard dose At autopsy the CSF was still turbid and there was a fibrinous exudate at the base of the brain Samples taken at autopsy gave the following levels of free drug per 100 c cm heart-blood 33 8 mg , pericardial fluid 31 8 mg , muscle 18 mg

The remaining patient, a girl of 7 years, was admitted in the third week of meningitis having been inadequately treated with sulphapyridine She was extremely emaciated and had intractable cerebral vomiting Treatment consisted of an initial intravenous injection of 2 g of the sodium salt of sulphamethazine followed by intramuscular injections of 2 g every 6 hours In all, 23 intramuscular injections were given and careful examination of the injection sites showed no sign of reaction At the time of writing very satisfactory progress has been made by the patient but the question of complete recovery is still doubtful

Lobar pneumonia —Six patients aged 1 year to 13 years responded well to sulphamethazine The patient of 13 years developed a type I pneumococcal empyema All recovered

A miscellaneous group of 5 ill patients were given sulphamethazine and are included in the total number because they were fully investigated, but the clinical diagnosis is not relevant in the present account

SUMMARY

A preliminary trial of sulphamethazine in children is reported

High blood concentrations of the drug were safely obtained with the experimental dosage used It is for further investigation to determine the necessity for such levels

[1] Macartney, D W Luxton, R W , Smith, G S and Ramsay, W A *Lancet*, 1942, i 639

[2] Colebrook, L *Ibid*, p 760

The therapeutic efficiency of sulphamethazine in a small series of cases of bronchopneumonia and meningococcal meningitis was encouraging.

The same low toxicity reported in adults was observed in children and infants. Other advantages over sulphapyridine are easier oral administration with longer intervals between doses, and much less likelihood of trouble at the site of intramuscular injection when the sodium salt is used.

We are grateful for the advice of our colleagues in the Crumpsall Hospital Laboratory, where all the bacteriological and biochemical investigations were made, and we thank Imperial Chemical (Pharmaceuticals) Ltd. for supplying us with sulphamethazine.

TRICHLORETHYLENE ANÆSTHESIA

JOHN ELAM, B.A. CAMB., M.R.C.S.
VISITING ANÆSTHETIST TO THE WELLHOUSE HOSPITAL, BARNET

IN June, 1941, Hewer and Hadfield[1] published a preliminary report on the use of a purified form of trichlorethylene known as 'Trilene' (I.C.I.) as an anæsthetic agent; these investigators found the drug satisfactory. A further report was read at the Royal Society of Medicine on March 6, 1942, by Hewer.[2] Since the first report I have used trilene or supervised its use, in over a thousand cases. Trilene is a very heavy liquid, vaporising much more slowly than chloroform or ether. It is non-irritating and non-inflammable; it has a smell not unlike that of chloroform. It is now coloured blue to distinguish it from chloroform, which is often coloured red.

Certain mysterious deaths have taken place among industrial workers who have to use trichlorethylene; it is thought that these were due to impurities. The post-mortem reports of two recent deaths in industry were unsatisfactory and no real explanation was given of their cause. Some workers in trichlorethylene are considered to be liable to aplastic anæmia. Whatever the cause of recorded deaths, no anxiety as to the patient's safety has been experienced in the 1000 administrations under review.

Trilene dropped on an open mask does not give a satisfactory anæsthesia because it vaporises too slowly, but if it is placed in the chloroform bottle of a Boyle's machine and given in conjunction with gas and oxygen a satisfactory light anæsthesia is obtained. Marrett, at the R.S.M. in March, showed an inhaler which he had devised by which air was inspired by the patient through a bottle containing trilene. Trilene may also be given from a Shipway apparatus. The anæsthesia obtained is in some ways like that obtained with chloroform except that full muscular relaxation is not uniform.

The similar composition of trichlorethylene and chloroform led to the fear that the new drug might have similar dangers, but so far this has not been the case. There has been no evidence of primary cardiac failure during induction with trilene, there appears to be no danger from its readministration, and there has been no evidence of delayed trilene poisoning.

The main features of the drug have been these. It is very easy to administer and is particularly suitable for general-practitioner work. Its administration over a long period appeared to cause no shock. (The longest administration in this series was 4½ hours.) There is very little vomiting even after long administration. For operations such as amputation of the breast there is much less hæmorrhage than when ether is used. The respiration-rate increases considerably after the administration has been in progress a few minutes, but if morphia or a barbiturate is given as premedication this rise is not so noticeable and in many cases is absent altogether.

For major abdominal operations trilene alone does not give sufficient muscular relaxation, but it is very useful in the induction period, gas-oxygen-trilene being used and ether added to obtain the required relaxation.

I would especially call attention to its use in midwifery for it appears to have very little effect on the uterine muscle, and a weak mixture of trilene and air will give an analgesia similar to that obtained with gas and oxygen. Other operations in this series in which trilene has been found most satisfactory have been operations on the skull such as depressed fractures (the patients were bad risk cases, but gave no anxiety whatever), operations on the nose and throat, and dental operations. Trilene gives enough relaxation of the jaw muscles to enable a large gag to be inserted for tonsil or mouth operations. It is a great comfort to both surgeon and anæsthetist to work with a non-inflammable anæsthetic, which does away with the risk of fire or explosion from lights, cauteries or suckers. Because of its property of not increasing hæmorrhage trilene made operations on the thyroid easier, and the absence of vomiting afterwards was a comfort to the patients. No attempt has been made to use trilene for intrathoracic surgery, although it has been successful for opening and drainage of empyema. It is always difficult to anæsthetise an empyema patient with gas-oxygen only, unless he has been carefully premedicated, and one is often asked to give these anæsthetics as an emergency. For orthopædic operations, especially on aged subjects—for example, the insertion of a Smith-Petersen pin—gas-oxygen-trilene is particularly suitable.

With the Boyle's apparatus in use at most hospitals today it is difficult to give pure gas and oxygen anæsthesia to the resistant patient and to keep him a good colour. The addition of trilene to the gas and oxygen makes just the required difference and does not appear to upset the patient. There are very real dangers in trying to do too much with gas and oxygen, as American anæsthetists have shown, and trilene seems to be the drug we have been looking for to enable us to avoid these dangers.

Manufacture presents no difficulties, though the supply is limited at present because such large quantities of trichlorethylene are being used in industry.

SUMMARY

Trichlorethylene, or trilene, has been used as an anæsthetic in over 1000 cases. There have been no deaths which could be attributed to the anæsthetic. Its non-inflammability, ease of administration and absence of postanæsthetic vomiting make it a satisfactory anæsthetic when full abdominal relaxation is not required.

It is useful in conjunction with gas and oxygen for increasing the depth of anæsthesia.

About half the cases in this series were anæsthetised by medical students, to whom I am indebted for their help.

Reviews of Books

Victorian Doctor

The Life of Sir William Wilde. T. G. WILSON, M.B., Litt.D. Dubl. London: Methuen. Pp. 338. 15s.

To call Sir William Wilde a Victorian doctor hardly does justice to the sort of man he was; but then Dr. Wilson's notion of the Victorians differs a good deal from the conventional one. Thus he writes, "After all, Wilde had only two faults: his bad temper and his mistresses. In extenuation of these we may plead his many good points and remember that he lived in an immoral age, for all the Victorians were not good by any means." No doubt; but Victorian Dublin was so different from Victorian London at any rate, that the adjective becomes too protean. It is customary to lament the decay of "characters"—of eccentrics and men with enough originality and independence to do as they liked; whether this is a needless regret or not, no-one could have had occasion to feel it who lived in Victorian Dublin and was familiar with the circles in which Wilde and Speranza moved. Neither Wilde nor his wife deferred to convention, and the famous trial—ominous of his son's catastrophe—would have done little harm to a more respectable man. W. B. Yeats said that the Wildes were "dirty, untidy, daring . . . and very imaginative and learned." Dr. Wilson's entertaining narrative gives body to these adjectives, and pictures a man of great ability and energy of mind who worked fruitfully at archæology, vital statistics and his specialties of otology and ophthalmology. It evokes also a picture of Dublin during the middle of the last century, which makes one, sorry that its glories are now dimmer, and its witty talkers and controversialists somewhat further from us THE LANCET, it is pleasing to recall, championed William Wilde during his trial, earning for its report, from the cantankerous editor of the *Dublin Medical News*, such epithets as "hissing-hot rhodomontade," "safe, because unproveable innuendo"

---

[1] Hewer, C. L. and Hadfield, C. F. *Brit. med. J.* 1941, i, 924.
[2] Hewer, C. L. *Proc. R. Soc. Med.* 1942, 35, 463.

Some of Dr Wilson's speculations about endocrine anomalies in the Wilde family have little to support them, and he is naive in his belief that people with repressed homosexuality are quick to recognise or accept it in others But his medical like his other carefully assembled facts are otherwise admirably set forth the book is a lively, accurate, well-written chronicle of a remarkable man, living in a remarkable city

Modern Treatment of Syphilis

(2nd ed) JOSEPH EARLE MOORE, MD, physician in charge, syphilis division of the medical clinic, and visiting physician, Johns Hopkins Hospital, Baltimore London Baillière, Tindall and Cox Pp 674 38*s* 6*d*

THE first edition of this monograph by Dr Moore and his colleagues appeared in 1933 and received a warm welcome The present edition is modified in the light of knowledge gained in the past eight years It draws extensively on the clinical material studied by the Cooperative Clinical Group in general and that of the syphilis division of the Johns Hopkins Hospital in particular, but other sources are not neglected, as an authors' index of 11 pages bears witness The presentation is concise and the text benefits from the many tables and diagrams There are 33 chapters presenting the biology of syphilitic infection in relation to treatment, the prognosis of untreated and treated syphilis, the therapeutic problem in the individual patient, the antisyphilitic drugs, technical procedures and possible reactions, the treatment of early acquired syphilis and the later stages, latent or manifest in different organs and systems, syphilis complicated by pregnancy, congenital syphilis, the interpretation of serological tests (by Dr Harry Eagle), the therapeutic test, syphilis in relation to marriage and public health, the prophylaxis of syphilis and, finally, an appraisal of the present position of the intensive method of arsenotherapy

The sound principles propounded should do much to raise the standard of syphilis treatment in the United States where many patients are treated by general practitioners In this country the book will be chiefly appreciated by venereologists in the special centres, who treat the great bulk of cases They may be surprised at the emphasis attached to the use of arsphenamine ('606') in early syphilis and may remain unconvinced by the arguments advanceed in favour of the continuous alternating method of treatment The intermittent method used in Britain gives good results and it is possible that American critics of the method have failed to distinguish carefully between results of properly planned intermittent treatment and those following irregular treatment Diagnosis of congenital syphilis is discussed and the difficulties are emphasised of interpreting a positive serological result during the early neonatal period in infants born to women whose serum also gives positive results The induction of malaria in the therapy of neurosyphilis in this country is now often effected by the inoculation of infected blood, and Moore's statement to the contrary (p 375), based on a reference published in 1925, requires modification But the author would get full marks in Colonel Harrison's catechism (*Brit J vener Dis* 1942, 18, 71) and the monograph is warmly recommended to all those who treat syphilis in civil and Service patients

Vade Mecum of Medical Treatment

(3rd ed) W GORDON SEARS, MD Lond London Edward Arnold Pp 371 10*s* 6*d*

FEW subjects are more difficult to compress into a small space than that of treatment Advice on therapeutics should be detailed Dr Sears has clearly realised the danger, even if he has not been able to avoid it fully Despite his warning against the claims of the manufacturing chemists the book mentions a fair sprinkling of proprietary preparations, many of them little known He is also rather fond of such general phrases as "... may be given if desired," "... the effect is doubtful, but it can do no harm," and a "vaccine may be indicated" The reader would welcome more dogmatic advice But in the main he gives well tried standard prescriptions—in some instances perhaps even allowing tradition to outweigh reason and experiment For example when he discusses hæmatemesis he does not make it clear whether he recommends Meulengracht's method or not, and the reader is left to judge that initial starvation for 36 to 48 hours, followed by 1 oz feeds 2 hourly, working up after a week to 5 oz every 2 hours, is the method of choice In future editions it might be worth adding pruritus and cough to the symptoms dealt with, and including some of the drugs recommended in the index A table of modern—especially British—proprietary preparations would be useful

A Practical Manual of Diseases of the Chest

(2nd ed) MAURICE DAVIDSON, DM Oxfd, FRCP London Humphrey Milford, Oxford University Press Pp 575 42*s*

MUCH has happened in the chest world since the first edition of this book was published 5 years or more ago the sulphanilamide group of drugs has been generally applied to pulmonary infections, the extrapleural pneumothorax has come (and almost gone), fresh advances have been made in the methods of giving oxygen, and there has been a deeper appreciation of the mechanism and consequences of pulmonary collapse The accounts of all these subjects have been amplified in the second edition, and the section relating to atelectasis and bronchiectasis—a subject on which Dr Davidson is especially qualified to speak—has been entirely rewritten in the light of modern work The book is not only a practical manual of the whole field of chest medicine but covers the broad principles of chest surgery too, in the sane and common sense manner exemplified by the author's assessment of the true significance of thoracoplasty in the treatment of phthisis

Clinical Atlas of Blood Diseases

(5th ed) A PINEY, MD Birm, MRCP, S WYARD, MD Lond, FRCP London J and A Churchill Pp 134 16*s*

THIS familiar little book has been revised and is now a veritable textbook of hæmatology in miniature The two plates of bone-marrow smears are disappointing and not very clear, this is especially true of the marrow of pernicious anæmia in relapse, in which the characteristic open network of the megaloblasts has failed to reproduce The plate of eosinophil myelosis seems redundant and is nothing like as good as the plate which illustrates eosinophilia Very few cases of idiopathic hypochromic anæmia have a blood picture like that shown The treatment sections are generally sensible, but splenectomy is surely drastic for so vague a syndrome as chronic agranulocytosis, and mocassin snake venom is not now recommended for thrombocytopenic purpura On the whole, however, this book maintains the usefulness that has kept it before the medical public for 12 years The production is first-class and the price for a book containing so many colour plates is remarkably low

Air Raid First Aid

W A ASHFORD London Williams and Norgate Pp 46 1*s* 6*d*

THIS stiffly bound booklet summarises the essentials of first aid as presented to a first-aid party at an incident It does not attempt to cover the ground of the ordinary textbooks but supplements them, and in some instances it modifies standard teaching The author has clearly had first-hand experience of the blitz and he has put it to good use The material is presented in a clear and simple fashion and will be useful to all who have to treat air-raid casualties There are a few misleading statements for example, the novel explanation for grey asphyxia, "the red corpuscles are turning white through need of oxygen" Then bandaging a fractured patella without splints is recommended if the patient is reasonably near hospital and this is quite unsound The misconception, so widespread among first-aiders, that saline is an antiseptic rears its head again Apart from these three bloomers, serious though they are, the pamphlet is worth having because it brings into sharp focus the special conditions of air-raid work

THE LANCET

LONDON SATURDAY, SEPTEMBER 12, 1942

PERSONAL FACTORS IN ACCIDENTS

THE terms of reference of the Industrial Health Research Board, both in the past and as recently revised (see p 326), have naturally laid stress upon the importance of the board making widely known in industry those results of its researches which are capable of application With this end in view it has adopted during the war an issue of emergency reports which, with a minimum of technical details, review the work published in full in its prewar report series The latest addition deals with the personal factor in accidents[1] With the employment of greater numbers of people, many of them young and inexperienced, many on dangerous work, there has naturally been a large increase in industrial accidents, and attention to some of the factors involved is therefore timely Such factors may be divided under two broad headings—general and personal The general ones include such features as the hours of work, the heating, ventilation and lighting of the factory, the experience, age and fitness for work of the employee, and the attitudes of both the management and the workers , the personal include the individual differences between workers in accident-proneness

In the last war excessively long hours of work were found, as would be expected, to lead to an increased accident rate , though long hours are, to some extent, inevitable under war conditions their effects may be partially offset by rest pauses, changes of occupation and similar relief measures Inexperience may be let down lightly by a planned absence of exposure to special dangers during the process of learning and adaptation New entrants, too, should not be allowed to pick up the technique of their occupation in the ordinary course of production Training schemes often appear to be wasteful of time, especially for simple processes, but they often save time in the end by turning out workers who are more productive and less liable to accidents Such methods are likely to be particularly fruitful with the young worker On the other hand, elderly workers have to learn a new set of muscular habits when their physical efficiency and general quickness of uptake have begun to decline Their employment on jobs demanding very rapid movement is clearly undesirable Equally obvious is the need for attention to efficient passageways for the movement of goods and raw material, and to the height of work benches Obvious, indeed, all these precautions may be, but they are not always regarded in a drive for production which sometimes leads to the view that a toll of accidents is inevitable It is true that action based on such simple characteristics of industrial life may well have considerable effect on the incidence of accidents

Much more difficult is the problem of the accident-prone Statistical research has shown—as was long dimly recognised in practical life—that even given equal exposure to risk people are not equally liable to incur accidents, but the crux of the problem is to recognise the prone before they do themselves or others harm For nearly 20 years the board's investigators have been experimenting with tests, with some success in skilled, though not in unskilled, occupations In the former the æsthetokinetic group of tests, involving rapid and accurate hand and eye coordination, has been the best line of approach, though even here the correlation between ability to perform the tests and accident incidence is unfortunately not close enough to ensure that the small minority who will have most accidents will be surely detected An alternative, or rather complementary, method is the accurate recording of the number of accidents sustained by each individual during a specified period of exposure Though sometimes the door must be shut after the horse has gone there will be many instances in which the worker can be diverted on the basis of his experience, especially in the early stages of industrial life, to work where the accident risks are less The most effective procedure lies, the report suggests, in a combination of these two procedures—first selecting by means of the psychological tests and then at the end of an initial period removing from risk those with an unduly high accident rate All the accident-prone will still not be detected and injustice too may be done, but it will not be a serious injustice if the worker can be moved early in his career without loss of prestige or pay There is no question of not employing those believed to be accident-prone, they can be usefully employed in many occupations An essential is a careful recording of all accidents, however slight, and this clearly written report ends with a specimen form for the purpose Its widespread use would produce necessary data for further research as well as achieving the specific purpose of seeking out the accident-prone and focusing attention on work carrying particular risks of either minor or major accidents

TRAINING FOR CHILDBIRTH

THERE is a very old and widely held belief that intensive physical training in women interferes with the reproductive functions Even in recent times every development in the athletic training of girls has had to fight not only popular prejudice but professional disapproval Quite mild gymnastics or ball games have been credited with all sorts of evil consequences, from dysmenorrhœa to sterility And long before gymnastic mistresses were thought of, female circus-performers were darkly suspected of inability to bear their children normally—if they conceived at all These allegations, so detrimental to a free and healthy life for girls and women, were never firmly based on a scientific theory of movement, nor were they borne out by any statistical evidence It has never been clear why improved suppleness of the joints, or well-developed abdominal and pelvic muscles should inhibit childbearing It is the flabby, idle woman who is the obstetrician's bugbear There are no easier labours than those of peasant women who spend their lives in much heavier physical exertion than the keenest gymnastic mistresses The dangerous possibility seems to be that certain " stunts," more common among circus performers than among gymnasts, might conduce to perineal rigidity or uterine displacement In view of the importance of avoiding any methods of physical culture which would interfere with the chief function of women, investigation was overdue, and there is every reason to welcome the inquiry into the effect of gymnastic training on childbearing carried out by a joint committee of the Medical Women's Federation and the Ling Physical Education Association

---

[1] Emergency Report No 3 H M Stationery Office, 1942 pp 19 4d

The Ling Association have for long been keenly aware of the responsibility which rests on the physical advisers of the future mothers of the race With this in mind, their training methods have been substantially modified in recent years to increase muscular flexibility and harmony Every effort is made by the modern gymnastic teacher to avoid producing rigidity or excessive muscular development of any part The results of the inquiry, as summarised by Dame JANET CAMPBELL in the published report,[1] show a considerable measure of success The inquiry had to surmount many difficulties, some inherent in the subject and others due to war conditions The heads of the principal physical training colleges were asked to get into touch with former students and obtain their replies to questionnaires drawn up by the committee Each student was also asked to find a sister or other relative to fill up a similar form and thus to act as a control Returns were made by 759 gymnasts and 423 controls, a number too small to satisfy a statistician but enough to give a fair picture of obstetrical conditions in a representative group The returns were classified according to the age of the women at marriage and the duration of the marriage—whether more or less than 15 years The gymnasts shared no significant differences from (or even compared favourably with) the controls as regards health in pregnancy, length of labour, amount of instrumental interference, percentage of complications and perineal damage The number of live births in each group shows that their fertility was about equal Only in respect of the number of stillbirths and miscarriages were the gymnasts at a disadvantage There were 36 stillbirths and 182 miscarriages among the gymnasts as against 10 stillbirths and 84 miscarriages among the controls As Dame JANET points out, this question calls for further investigation, as the possibility of association with greater physical activity cannot be excluded The report does not say whether the gymnasts continued their activities after marriage, so no useful deduction can be drawn at this stage

If the inquiry, limited and incomplete as it inevitably was, has proved reassuring in regard to the physical training of women, it is less satisfactory in the light it throws on the practice of midwifery and the exercise of the reproductive function in a sample group of women of the professional class For this purpose the gymnasts and their controls may be considered together. In the first place, these women of good stock and superior physique are not reproducing themselves Even among the group who married between 20 and 24 and have been married over 15 years, the average size of the family is only 2 95—less than enough to maintain the population at its present level The other groups had even fewer children This is not due to loss of fertility, for out of 97 women whose marriages were childless 43 stated that the sterility was intentional; 46% of all the women admitted to using contraceptives before the birth of the first child and 67% after the first birth Again, the amount of artificial feeding is disappointing in women who must all or nearly all have had much hygienic teaching Less than half the mothers in some groups suckled their children and the highest percentage was 77% among some of the controls, but these figures are subject to reservations and qualifications This is not a war-time or even a recent phenomenon, for the older women had a worse record than the younger ones The most disquieting revelation however is the amount of instrumental interference to which these mothers were subjected Among the primiparæ it varied from 23% to 5% in the women married when over 30, and even in multiparæ it is nowhere below 6% Dame JANET CAMPBELL points out that the data do not enable us to say whether the forceps were merely used at the end of labour in an otherwise normal birth or for some definitely abnormal condition In any event the figures should cause some searching of the heart among obstetricians The reports of voluntary and municipal hospitals, and of the domiciliary midwifery service, show that forceps deliveries among working people constitute less than 5% of the whole—sometimes much less The aim of every antenatal clinic is to give a mother the courage and capacity to deliver herself Is there such a thing as "class midwifery"? Either the working-class woman is entitled to more instrumental aid to relieve her sufferings or the middle class woman should do with less It seems unlikely that the public at large will listen to hygienic advice from the professional classes if their women-folk do not carry it out themselves A poor man's wife has presumably as good reasons for limiting her family to a degree which threatens the national existence, for refusing to breast feed her infant and for demanding instrumental aid in delivery, as these gymnasts and their sisters This inquiry gives a valuable hint on how propaganda could most usefully be directed

THE SOLDIER'S FOOT

PAIN in the feet is one of the commonest symptoms confronting the regimental medical officer, and, as an official bulletin[1] puts it, it is his duty to keep good feet symptom-free rather than render those with gross deformities fit for service The most that can be demanded of the soldier's foot is that it should be supple, painless, of adequate musculature and free from gross deformity; when these qualities are present minor degrees of hallux valgus, hallux rigidus, pes planus and cavus need not remove their owners from the A1 category Pain is the foot's main safeguard, and untreated may lead to habitual malposture and recurrent foot-strain; the MO can usefully detect the minor alterations in gait and behaviour suggestive of unreported trouble and elicit the cause In Army life there are three periods at which pain may arise—on enlistment, at PT and after route-marching On enlistment, the change from light civilian shoe to heavy Army boot throws a temporary strain on the tibialis anterior which may develop into a chronic fatigue with diffuse pain referred from tender points in the muscle, or an acute tenosynovitis may be set up The long extensors of the toes then tend to help in dorsiflexion of the foot, so that the toes become sore and callous from rubbing against the toe-cap and a valgus foot is eventually produced with clawing due to simultaneous use of all the extensors This is the incoordinated foot which, as Crisp[2] says, the owner uses as a cow its hoof During route-marching an acute foot-straining occurs, often in association with tender nodules in the plantar fascia and flattening of the metatarsal arch, and these feet must be rested until completely painless In physical training a symptomless hallux rigidus is often provoked by certain exercises The soft plimsoll is pernicious in this respect, and the stiff shrunk sock encourages any tendency to clawing of the toes The bulletin emphasises that the length of treatment is proportional to the duration of symptoms, so that early reference to an orthopædic surgeon is desirable Crisp points out that, while a minority of foot cases have entered the Army with glaring defects in too high a category, most of the trouble is due to the breaking down of apparently normal feet during training The Army boot is comfortable and harmless to the normal foot, but aggravates any tendency to weakness, stiffness or incoordination, and the speed at which gross deformities may develop and become fixed is astonishing A previously weak foot may develop an acute planus which requires long rest and careful re education in hospital for 6–8 weeks, while the stiff civilian foot will tend to break down again and again under Army conditions until the patient is hospitalised, rested and the foot manipulated Re-education is particularly required for the valgus foot with clawing due to incoordinated extensor action already mentioned, and once these patients have re-learnt the use of their intrinsics and to dissociate dorsiflexion from extension of the toes they are well on the way to recovery The main lesson to be drawn from a study of the large amount of material provided by the war is that the painful foot is a major disability which usually requires hospital treatment, incomplete outpatient supervision leads too often to a vicious circle of recurrent pain and stiffness Preliminary bed-rest is necessary for the majority, and individual attention from the physiotherapist should precede participation in the general foot-class In few other disabilities is the end-result affected so largely by the patient s willingness to cooperate and general morale, and a preliminary report by the RMO on the man's character assists in deciding between palliative and radical treatment, or whether re-grading is necessary

THE DYSENTERY BACILLI

Bacillary dysentery may be caused by any one of a group of non-motile gram-negative bacilli, of which the principal members are named Shiga, Schmitz, Sonne and Flexner The first two—differentiated from the others by their failure to ferment mannitol and Schmitz from Shiga by its production of indole—are rare causes of dysentery in this country, Schmitz has been found in outbreaks of asylum dysentery and occasionally from sporadic cases outside mental hospitals, and Shiga is imported from abroad—it has lately been recovered from symptomless Italian prisoners of war[3] The Shiga, Schmitz and Sonne bacilli, the last type associated with an enteritis often unaccompanied by blood or mucus, are each single antigenic entities The Flexner bacillus, on the other hand, is an antigenic family, the members of which have their own specific antigen but share, in addition, a common group antigen which links them together Boyd[4] found that on repeated culture in the test-tube the specific antigen tends to disappear, leaving behind the group antigen As a result, the Flexner type Y of Andrewes and Inman,[5] which contains only group antigen, drops out as a specific type, as does X which Boyd regards as an incomplete variant of Z, but the family is augmented by three new types—type 103 which has a wide geographical distribution and has been found in this country, P 119 occurring in India, South Africa and the Far East, and the well-known Newcastle bacillus which is now endemic in certain parts of this country and differs biochemically from all the other members of the Flexner family in not producing indole and usually fermenting dulcitol as well as glucose with slight gas-formation Boyd suggested that these six members of the Flexner group, the V, W and Z types of Andrewes and the three new types 103, P 119 and Newcastle, should be called *B dysenteriæ* Flexner I–VI, and the Army Medical Service has adopted this new and simplified nomenclature In addition, Boyd has isolated in India a number of antigenically distinct mannitol-fermenting dysentery bacilli lacking the Flexner group antigen, and for these the name *B dysenteriæ* Boyd I, II, III &c is suggested

The isolation and identification of the dysentery bacilli has lately been made much easier by the use of new media and technical methods Formerly, isolation of the pathogen was easy only in the acute stage of the infection, and even then, because the dysentery bacillus was supposed to die very quickly, it was often advised to bring the bed-pan with the freshly voided stool directly from the ward to the laboratory Now, with the use of desoxycholate-citrate agar[6] which inhibits the growth of most coliform organisms, the dysentery bacilli can be isolated even when they are greatly outnumbered by *B. coli*, as happens in convalescence or in contact carriers or when the fæces have lain for some time before cultivation Contrary to current teaching, the Sonne dysentery bacillus will survive in fæces or on a moist rectal swab for several days at atmospheric temperatures of 15–20° C, and observations reported by Cruickshank and Gillespie in a letter on another page have established a similar viability for the Flexner bacillus At higher temperatures, such as may obtain in Egypt and India, the organisms die out more quickly so that the buffered glycerol-saline preservative should be used if there is likely to be much delay in getting the specimen to the laboratory, or alternatively the rectal swab dipped in saline agar may be tried The heavy growth on the desoxycholate-citrate agar makes it easy to pick off colonies for direct slide-agglutination with the appropriate antisera Few strains of the Sonne or Flexner races fail to agglutinate in this way, but with new cases confirmation from the biochemical reactions may be sought by subculture Serological subdivision of the Flexner group is not ordinarily required but may be essential epidemiologically for tracing sources of infection Monospecific sera can be readily prepared by absorbing out the group agglutinins Thus with modern methods the bacteriologist can make or confirm a diagnosis of bacillary dysentery within 18–24 hours of receipt of the specimen, without much fuss and with an accuracy approaching 100%

be gained by giving standardised tests of motor control, such as those of Ozeretzki, to backward children She notes the performance quotient obtained by giving the Drever Collins tests to individual children, but has compiled no statistics of such quotients for the whole group of children showing laterality Results would also have been interesting of a non-linguistic test of reasoning ability, such as the Raven progressive matrices which have been used successfully with deaf children The investigation, indicating as it does the importance of an essentially physiological factor, offers scope for further study, and may have a practical bearing on educational method

THE NEW CHAIR OF CHILD HEALTH

SOME £3 million a year are spent in this country on child welfare and about another £4 million on school medical services The money devoted to the teaching of pædiatrics is by comparison negligible, yet about a third of the general practitioner's patients are children and the officers of the child public health services should surely be offered opportunity for postgraduate study The money spent on research into the diseases of infancy and childhood is also infinitesimal, yet, as was suggested last week, we do not know nearly enough about how and why infants die There is with reason a growing feeling abroad that to spend large sums on the study of the diseases of old age and so little on the diseases of children and infants is to begin at the wrong end of the stick The Nuffield Trust—always sensitive to the stirrings of wisdom—has now come forward with a gift of £15,000 to the University of Durham towards the cost of establishing a professorship of child health at King's College, Newcastle on-Tyne, and Dr J C Spence's appointment to the chair is announced on another page The university intend to provide him with the assistance necessary to create a full teaching and research department, and the Royal Victoria Infirmary and the Babies Hospital will join with King's College in providing facilities for the new department, which will also be at the disposal of local public health and education authorities for advice and consultation on the conduct of their child welfare and school medical services In the region's varied populations—urban, mining, industrial and rural—Dr Spence and his assistants will find comprehensive teaching material and opportunity for varied field work

BLOOD-VESSELS AND THEIR ENVIRONMENT

Prof Rene Leriche,[1] working now far away from his famous clinic in Strasbourg, has been studying the behaviour of blood-vessels in response to pathological environment He reviews vasodilatation in its clinical bearing on the symptoms of cervical ribs , on resection of arteries , on sympathetic nerve resection , and particularly on the enlargement of vessels in the neighbourhood of arteriovenous aneurysms Inaccurate observation and inaccurate description have often given the impression that the vessels below an arteriovenous fistula dilate passively in response to increased intravascular pressure Leriche confirms what is really apparent in some of William Hunter's original descriptions—that the enlargement is one of length as well as of breadth, and is associated with hypertrophy of all the coats of the vessel It is no localised sac like dilatation , moreover it can affect the vein as well as the artery, and it can hardly be conceived that the pressure conditions within the vein tally with those in the artery So enormous may the dilatation be that Leriche has seen a case in which the iliac vessels formed a tumour in the iliac fossa suggestive of an ovarian cyst No purely mechanical explanation will suffice to account for the long, tortuous, serpentine vessels found in such cases That the pressure is raised in the artery below the fistula is obviously not the whole explanation The aneurysmal dilatation of the subclavian artery sometimes found in proximity to a cervical rib is another example of the same process The structure of the whole vessel is affected, but the condition is not histologically an aneurysm it is not a local dilatation due to weakness of one coat of the artery nor does it behave clinically like an aneurysm—after removal of the rib there is no progressive dilatation because the wall of the vessel is not weakened Leriche does not believe in a mechanical origin of the lesion, but regards it rather as a local vasomotor effect He has improved the circulatory symptoms greatly by periarterial sympathectomy, in one case with associated lessening of the dilatation, and in another with its disappearance The change in the artery is to be regarded, he thinks, as physiological rather than anatomical Leriche describes a case with rapidly progressive symptoms of Raynaud's disease in one upper limb , radiography revealed a cervical rib which was removed, and at operation the subclavian artery was found to be much dilated Arteriography, by thorotrast injection, showed that the brachial artery was not patent The operation did not relieve the vasomotor attacks, whereas a subsequent resection of the obliterated segment of the brachial artery, combined with a periarterial sympathectomy of the brachial below this point, was followed by recovery This case demonstrates that a localised arterial lesion can produce a distant lesion which may actually lead to obliteration of the distant vessel The vasodilator effect of sympathetic section is commonly supposed to be due to a paralysis of the vasoconstrictor mechanism , if this were so one would expect to find depression of the circulation in the affected part Leriche confirms Claude Bernard's observation that the effect, far from being paralytic, is an enhancement of the circulation He finds further support in the experiments of Fontaine who demonstrated by arteriography after thorotrast injection that unilateral lumbar sympathectomy in a dog caused greatly increased arterial circulation on the resected side as contrasted with the intact side Leriche, however, warns us against too easy comparison between the quick acting effects of experimental vasodilatation and the slow acting conditions of pathological environment , there is no real analogy A pathological environment gives time for active vasodilator substances to come into play, and Leriche rather favours this possibility His most notable conclusion is that the vascular system is a physiological entity which acts as a whole When one part is touched distant parts will respond " Life does not admit of the division into the compartments of our textbooks "

CHEMOTHERAPY OF COMMON FEVERS

STREPTOCOCCI and pneumococci play such important rôles as secondary invaders in the specific fevers that the possibility of control by chemotherapy has attracted many investigators Telegdi,[1] presumably in Hungary, has treated 1310 controlled cases of measles, scarlet fever and influenzal pneumonia with sulphathiazole and obtained good results in all three infections The mortality from influenzal pneumonia was reduced, particularly in the upper age groups In measles, the incidence of pneumonia and middle ear disease definitely decreased—a prophylactic result which now appears fully attested No effect was expected on the initial toxæmia of scarlet fever, so that combined treatment by chemotherapy and specific antitoxin was used Telegdi claims to have influenced particularly the onset course and duration of ear complications There is little doubt that established middle ear disease in scarlet fever is amenable to chemotherapy Whether chemotherapy can prevent otitis is less certain, the preventive value of sulphonamide drugs in scarlet fever having now been almost equally supported and contested by different observers On the whole, there seems no clear indication for routine chemotherapy in scarlet fever as long as it retains its present mild character

THE CANCER ACT*

RALSTON PATERSON, MC, MD EDIN, FRCSE FFR
DIRECTOR OF THE RADIUM INSTITUTE, MANCHESTER

THE application of the Cancer Act of 1939 in the immediate postwar years promises not only to have a profound influence on the evolution of radiotherapy but to affect the organisation of surgery Under the act every local authority becomes responsible, in regard to patients suffering from cancer, for seeing that the following are provided diagnostic facilities , adequate and efficient treatment both by surgery and by radiotherapy , a follow-up scheme with the necessary statistical records , suitable popular education or propaganda measures It is also indicated that authorities should collaborate in joint action and with such existing organisations as already provide facilities either wholly or partially

Before reviewing the methods by which these needs may be met, it is necessary to assess the number of cases likely to be involved Such an assessment is possible in malignant disease because the yearly incidence of cancer is remarkably constant, not only in total numbers, but in the numbers of each type of cancer We are therefore in a position to forecast requirements and to plan accordingly In table I such an analysis is attempted, aiming, where numbers depend on calculation at overestimate The Registrar-General's reports have been used for basic figures I have had to make a personal estimate of the situation as regards treatment Such a table can only be approximate, but it gives a good general idea of the problem The table is based on two assumptions first, that the best surgical and radiotherapeutic methods will be made available to all, but with no revolutionary improvements in their scope or effectiveness , secondly, that, short of a systemic test for cancer similar to the Wassermann, diagnostic achievement will not appreciably exceed that of present day work in good hospitals As will be seen from the numbers given in the table, this second assumption recognises that many of the common cancers, such as cancer of the stomach, will continue to be untreatable from the moment the patient is first diagnosed I do not feel that any form of organisation or of propaganda will alter this In terms of numbers for treatment, it is the four " accessible " cancers which are of greatest importance

Table I shows the maximum number of new cases per annum which will require treatment in a population of a million, and how they will be treated Column 1 shows the number of cases The number of registered cancer deaths is about 1650 per million per annum , one may reasonably add something of the order of 20% to these figures for failure of accurate certification and to allow for treated cured cases—at the present time a very low figure if taken over the whole population This gives us a reasonable estimate of the total number of new cancer cases per annum per million as 2000, divisible as to types in the ratio of the Registrar-General's figures for cancer deaths It is often argued that at any moment there are at least one and a half, if not twice, the number of cancer patients in existence as are diagnosed each year This is true but does not alter the fact that it is the number of new cases each year with which any organisation will be called upon to deal

Calculation of the fraction of new cases which will be amenable to active treatment is a harder problem Sholto Mackenzie[1] (now Lord Amulree) arrives at the number of cases of each cancer type actually receiving treatment in the country in the prewar years (column 2) It is probably safe to estimate that we will overstate the needs for the first 5–10 years of improved organisation if

TABLE I—ESTIMATED NUMBER OF NEW CANCER CASES PER ANNUM PER 1 000,000 POPULATION , PROBABLE ALLOCATION UNDER ADEQUATE ORGANISATION, WITHIN THE LIMITS OF EXISTING DIAGNOSIS AND TREATMENT

* Excluding basal cell carcinoma † Estimates only ‡ Taken from Mackenzie s figures

we take twice his percentages as our indicator—with 100% maximum of course, since more cases cannot be treated than occur The resultant numbers for treatment are shown in column 3 Then follows a section, showing probable methods of treatment under a well-organised scheme, to arrive at these estimates, I considered each disease separately and reviewed my own fairly extensive experience of present treatment methods in the light of the annual figures of the Radium Institute, Manchester, where a large part of the radiotherapy for a population of about five million is undertaken In the table rodent ulcer is entirely omitted, since it is difficult to arrive at any figure for this disease Any unit, however, will be called upon to treat a number of rodent ulcers as well, usually by simple methods in the out-patient department

---

* A paper read before the Faculty of Radiologists on June 6, 1942

[1] Mackenzie, B W S Rep publ Hlth medical Subj , Lond 1939 No 89

I have suggested the classification into three groups before [2] The curable cancers are those for which cure is possible in a worth-while percentage of all cases and in a high percentage of all early cases treated, the treatable cancers those in which cure is only achieved in a low percentage of all cases but in which treatment is essential in a moderate fraction The incurable cancers are those in which palliative treatment may be of some value, but cure is rare and likely to remain rare with present-day knowledge and diagnostic facilities The incidence and treatment of cancer per million population may be summarised in round figures from table I as follows

Incidence	
New cases per annum	2000
Untreatable from first diagnosis	900
Lengthy investigation, but not treated	>200
Maximum number requiring active treatment	900
Treatment	
Radical surgery	300
Radical radiotherapy	300
Palliative treatment	300
Cases needing some surgical treatment	600
Cases needing some radiotherapy	600
Beds required	
Average 4 weeks per patient, 900 treated	70
Average 2 weeks per patient, 260 investigated but not treated	10

It shows lack of realism not to admit that in the disease group generically called cancer there is still a large fraction which is incurable, nor is there any hope that this will be changed, except by some genuinely revolutionary discovery On the other hand, the established achievements of surgery and radiotherapy give us weapons by which some types of cancer can be cured if treated early and effectively Success or failure depends largely on the first main treatment, salvage from second or third attempts is very small To anyone familiar with what is happening today it is apparent that *effective* treatment in the *early* stages is the exception rather than the rule Two factors contribute to this failure First, delay in the patient's transit to treatment, he may delay in seeking advice through fear, his practitioner may delay through lack of experience of the symptoms or appearance of early cancer, and the hospital waiting-list may cause delay in admission Secondly, cancer is still looked upon as merely one of the diseases—almost as one of the chronic diseases—included in the scope of general medicine and surgery Few consultants concerned with either its diagnosis or treatment have any extensive experience of its particular problems The method of treatment to be adopted is determined far more by the fortuitous accident of the type of consultant to whom the patient is referred than by any adequate consultation machinery, and execution is seldom in the hands of anyone with bulk experience of a particular technique

If improvement is to be achieved, two general principles must be accepted in whatever organisation is built up that once cancer is suspected, action must be immediate, and that all specialists concerned with diagnosis and treatment are engaged in cancer work to such an extent that they really have special experience of that group of diseases The second can be realised only by the creation of a special cancer organistion to coordinate work in such a manner that adequate numbers of patients will be seen and dealt with as one group This would also make it possible to segregate enough radium and X-ray plant for the necessary flexibility in treatment methods But the most important argument lies in the gain in bulk experience of the specialty by a limited number of people The whole scheme would benefit if each of them was engaged in cancer treatment or diagnosis for at least half his working time

THE CANCER UNIT

It is, I think, inevitable, that the treatment of cancer will become a specialised branch of medical practice, like the treatment of tuberculosis and, to a lesser extent, of venereal disease, and no doubt objections will be similar to those raised twenty years ago against the inception of tuberculosis services If we disregard these, how could this specialty be organised to produce the best results and perhaps some visible impact on vital statistics? It is this ultimate structure which we should visualise now, as a guide in the transitional period

The cancer unit may take the form of a specialist hospital or be a department of a large general hospital, usually the teaching hospital of an area The general hospital is to be preferred on many grounds, provided that the cancer department has a distinct organisation of its own, separate from the hospital, on which local authorities and other hospitals are adequately represented. From each million of the population, a cancer department will treat about 900 new cases yearly and will, in addition, admit a number of cases for investigation only A million should be regarded as the minimum population which will carry a really efficient organisation The bedrock minimum must be set at half a million, and then only in geographically detached areas Efficiency probably steadily increases up to at least two million, since this allows for the maintenance of junior and senior medical officers in most of the specialties concerned, with sufficient material for each

The two main sections of the cancer hospital will be the radiotherapy section, and the surgical section in which will be included the various collateral specialties gynæcological, laryngological, genito-urinary, &c Of the 900 new cases per annum per million it will be found that, allowing for a number of cases treated by both surgery and radiotherapy, each section will be called upon to handle about 600 cases per million population served Diagnostic services will include radiodiagnosis and pathology, although they may be combined with the corresponding departments in the general hospital

The unit must finally come under one director In the period of development, however, there is much to be said for the two sections being separate, even to the extent of each having its own director Such directors must be of equal status, and must work together sufficiently to have some knowledge of each other's results, both must be members of the executive of the governing body, and each must have enough beds under his own control The position and status of such director has been well outlined by Professor Platt [3]

Radiotherapy section—It is impossible to have any separation between radium and X-ray therapy, and both must be in the hands of the radiotherapist Trained therapists of today have been recruited about equally from surgeons with an interest in radium, and radiologists interested in deep therapy Each type of recruit has had to learn the other half of radiotherapy New recruits must in future train in already established radiotherapy centres Transference of control of radium work from surgeons to therapists in the major centres in this country is well on the way, only in backward areas or undeveloped centres is radium therapy still a surgical preserve There must be a similar transference of control of X-ray therapy for malignant disease from the radiodiagnostician to the radiotherapist This is somewhat further from accomplishment, most radiologists in the larger centres now realise, however, that this transference is inevitable and in the best interests of the patient, and are choosing which half of their work they will retain Partly as an expression of this essential split and partly as a step in the aggregation of X-ray therapy plant into departments with multiple units, the various 200 kV deep therapy plants now scattered broadcast over the country in single units should be concentrated into major treatment centres

---

[3] Platt, H *Lancet*, 1942, i, 179

Surgical section —In contrast to radiotherapy, which is now partly centralised in many areas, the present surgical treatment of cancer is everywhere included with general surgery This decentralisation with its consequent lack of adequate numbers of cancer cases for each surgeon, is found both in the large teaching hospitals and the smaller hospitals Plans to centralise into one cancer unit with a limited staff will therefore meet powerful opposition at first, which will be augmented by the desire of the smaller hospitals to remain independent of the large general hospital to which the cancer unit may be attached Two expedient interim policies may be considered

1 All cases could be collected at the central teaching hospital but the general surgical organisation there could be left unaltered and the cases could be spread over the various surgical and specialist units

2 The right of autonomy in this matter should be conceded to the better organised hospitals, whether teaching or not, but they would be expected to work towards a segregation of cancer cases, and their distribution among a limited number of the members of each staff

The second is both the juster and the more effective and would enable a number of surgeons and specialists to give a large part of their time to cancer work Payment would be either directly, or indirectly from the local authority under the Cancer Act The ideal, however, remains complete centralisation of cases in the surgical section of a separate cancer department or hospital, with a selected staff, limited in number but genuinely experienced The number of patients requiring treatment per million population gives the clue to the number of specialists needed In a centre serving a million population one, two or, at the most, three general surgeons will be required, but only one representative of each of the other specialties, with resident or other junior assistance Even where a unit is serving two or three million the necessary additional members of staff should work directly under the man in charge of a particular specialty and not be additional officers of independent status

DIAGNOSTIC SERVICES

Difficulties of distance should not be made too much of when considering centralisation, they can be surmounted To reach the cancer case at an early stage the key-note must of course be decentralisation in the geographic sense, but not as regards personnel Multiple clinics must be established For treatment, the association of a hospital with the idea of cancer cannot be avoided but it is important that these outside clinics are neither called, nor even become known as, cancer clinics The only way to avoid this is to incorporate them in the existing outpatient-services This usually means that they will be held at voluntary hospitals, they might be called tumour clinics In table II the basic figures from table I are presented again from the diagnostic angle Allowance must be made for cases examined but not treated, either because they are non-malignant or are too advanced for treatment A more than adequate approximation will be to take 150% of the numbers likely to come to treatment Groups 2 and 3 will for the most part require admission to hospital for the necessary diagnostic procedures The clinic medical officer has therefore only two tasks to perform to recognise as probable cancer any lesion which he can either see or feel (a biopsy being made in doubtful cases except in breast cancers), and to recognise the type of symptom-complex which merits special admission for investigation as potential cancer This is not a task which calls for a team of specialists It can be done by one man, provided that he has experience and is doing a lot of it In a completely centralised cancer service it is unimportant whether he be a surgeon, radiotherapist or physician During less centralised interim organisation, where radiotherapy is arranged by collaboration with a local hospital surgical service, it would be best that a radiotherapist should be in charge of the clinic because he will also have the responsibility of deciding, in collaboration with the local surgeon, between surgery and radiotherapy In about half the cases, including most cases of cancer of the cervix uteri, the diagnosis can be made by an experienced observer merely on sight or by simple palpation The other half of the cases will need admission to the central unit for examination, and it is at this stage that team collaboration becomes important From study of the types of case seen it is clear that consultation not between a whole board of examiners but between two people will generally be what is needed—usually between the radiotherapist and either surgeon or specialist or, less often, between the surgeon and a specialist Planning in the hospital should therefore cater for this two-person consultation Once diagnosis and treatment have been agreed on the case should pass for the time being into one person's hands as his exclusive clinical responsibility, and further consultations will be sought as they are indicated

TABLE II—NUMBER OF CASES PER MILLION FOR DIAGNOSIS (based on 150% of numbers treated)

Group 1		Group 2		Group 3	
"*Spot diagnosis*" Lesions visible or palpable		*Radiological* Diagnosis mainly by X rays		*Technical* Diagnosis mainly by special exam.	
Breast	312	Stomach	177	Pharynx and larynx	59
Mouth	116	Colon	125	Bladder	99
Skin	63	Œsophagus	45	Uterus (½ of cases)	67
Uterus (½ of cases)	133	Lung	27	Ovary	44
Genitalia	39	Bone	45(?)	Brain	45(?)
Rectum	100				
Totals	763		419		314

One person should also be allocated to pathological work and become highly experienced This is possible even if the work is done in the general pathological laboratories In many cases the pathological decision will be a key decision

Where a clinic is at a distance from the treating centre, follow-up examination will also be carried out at the clinic The visiting clinician must therefore be familiar with the points to look for in treated cases It may be argued that cases are thus lost for study by the people responsible for their treatment, but the clinic held at the centre itself is bound to be the largest, and will provide a sufficient sample for study; in addition, a good records system puts the entire clinical material at everyone's disposal Diagnostic clinics must be so widely distributed that no patient faces difficulties or hardships in getting to them Clinics should be held at least fortnightly at each place

EDUCATION AND PROPAGANDA

The first essential of any propaganda scheme is that it shall be simple and driven home by constant reiteration There are four curable types of cancer (breast, mouth, skin and cervix uteri), treated early these diseases are curable in 80% of cases, treated late in barely 10% Diagnosis is not really a problem—the growth can be seen or felt The key sign or symptom of each disease at its early stages can be described in two or three words

Breast —Take thought for a lump in the breast

Mouth and skin —Get advice about a small painless sore which does not heal

Cervix —Bleeding after the change of life is dangerous, before the change irregularities must be investigated

In no other types of cancer will education or propaganda, apart from improvement in medical education, have any really great influence In stomach cancer—the great killing cancer—the disease is often advanced at the time of the first definite symptom I believe that it is only in the four accessible cancers that, through propaganda, we can sensibly lower death-rates Nothing medicine has done so far as had the least visible effect on cancer death-rates My plan would be to harness the propaganda organisation to one task—that of putting across to the public the key symptoms of these four diseases If we found that we could alter the vital statistics of these diseases we would know that the methods had been successful When any other type of cancer became controllable a practised organisation would be ready to spread the information

THE LATE CASE

What about the late cases—either untreatable or after treatment has failed? They must not be dealt with in the same wards as cases undergoing active treatment Should they go into "cancer hospitals" to die? Most of them would be happier if nursed in their own home, and it would be a fine addition to the Cancer Act if some effective scheme of home nursing could be devised and carried through by local authorities, it would need to be a much more elaborate scheme than the daily visit of a district nurse Nevertheless, it is important both from the social and from the humanitarian point of view

WHO GETS THE LION'S SHARE?

It is reasonably easy, under a rationing system, to assess the average share of food bought for a family every week, but who eats what, at the family table, is often settled more by custom and tradition than by individual need Mr F Le Gros Clark has made a study[1] of food allocation in 40 working-class households in respect of meat, cheese, fish, eggs and milk—that is, of first-class protein He finds that the old belief is still prevalent that the wage-earner doing vigorous work needs meat or its equivalent so that the father generally gets more than his ration of meat, cheese fish and eggs, and the mother and children go relatively short Milk, however, is well recognised as a food for children, and they get the lion's share of that Le Gros Clark's inquiry was made in Edinburgh by an experienced social worker who was on familiar terms with most of the housewives In order that the replies should not be coloured in any way the housewives were told that a study was being made of the relation between home and communal catering

The 40 families, all of which included children, were visited during the winter months of 1941–42 There is no evidence that except in very low income families any member of a household normally goes short of calories, and vegetables, when bought, are thought to be fairly evenly shared out The inquiry was therefore confined to animal protein The foodstuffs investigated were all rationed, or virtually rationed, at the time of the inquiry, with the exception of fish which was not bought by all Of the fathers, 5 were builders, 6 brewery workers, 6 labourers in various trades, 2 engineers, 3 motor drivers, and 2 engaged in civil defence, 4 were unemployed, and the remainder had jobs about the docks, or were employed as shop-assistant, miner, and so forth, in 3 instances the mother was the sole wage-earner The average size of the family—considerably above the average for the country as a whole—was nearly 6 members

Cheese was bought by 36 families, 18 declared that they divided it equally among the members of the household, 9 allocated all, or nearly all the cheese ration, to the grown men in the family, usually in the form of "lunch-pieces" to take to work In the remaining 9 families practice varied There is a long-standing tradition that men and cats like cheese, but that it is bad for children That even young children benefit from cheese and cheese-dishes is a notion that is only slowly gaining ground Thus there is a heavy barricade of custom to cast down before cheese gets more fairly distributed in the family

Eggs stand in a different category they are recognised as being good for the child, but at the same time the wage-earner often fancies an egg to his tea The outcome, roughly, is that the father gets his share, or more than his share Eggs of course have been scarce, but the average allowance was one egg per head per week Most fathers contented themselves with a single egg, but in 2 families the father took no eggs, and in 9 families the father got two eggs or more, partly because eggs like cheese are handy for a carried lunch Of the mothers 7 gave up their eggs either to the father or the children, and the rest ate their ration, with the exception of 2 who admitted exceeding it In 27 of the families, then, the eggs were equally shared, in 33 the children received all or more than their share On milk, too, the children did well The mothers relinquished milk to the children almost automatically thus in 38 families the mother was getting less than half a pint daily, and this includes 3 who were pregnant, in 10 families where the mother took hardly any milk the children were getting well over half a pint each at home, and more at school One of these mothers was breast-feeding a child The fathers, too, took little milk, they were as abstemious in this respect as the mothers

Meat, however, was a different matter In many cases nearly half the family meat ration (not a very large one in any case) went to the father, and some had three quarters of it or more Those who received such large proportions either had some of it in the form of lunch pieces or were convinced that they needed it in order to perform their daily work Children under five get little or no meat, though they get gravy on potatoes Nearly half the mothers were getting less than a fair share of what remained when the father had taken his whack, and the children between 5 and 18 were getting perhaps 70–80% of their official ration Fish was only bought by 19 families but in those the father, though he had a large helping compared with other members of the family, did not exceed all bounds, and the mother and the growing children did fairly well

The estimates are admitted to be rough, but if it is accepted that about half the daily protein intake should be in the form of animal protein, then the average father in this small group of working-class families seems to be getting more than half his daily protein in that form, the mother and children less than half Adolescent children need more animal protein than their fathers if growth is to be normal—an idea which is still quite foreign to most working families In practice, however, many children of school age were getting school meals in addition to their food at home, and this brought their animal protein intake up to a proper level The mother's diet and those of children who have left school are more likely to be defective Le Gros Clark suggests that public attention should now be concentrated on the diet of young people between 15 and 25, especially the girls, who are apt to go short in favour of their brothers, and who seem, in the words of the Edinburgh investigator, "to be having a particularly lean time in almost nine cases out of ten" There is more than a suspicion that the rationing of animal proteins has told especially against those who are at the most vulnerable age for the attacks of the tubercle bacillus

A breakdown of the tradition that the worker needs the lion's share of meat could probably be achieved by propaganda and extended health teaching both over the air and by health visitors in the homes The factory canteen and the school meal, by replacing the lunch piece, can release first-class protein for a fairer distribution at the family table Le Gros Clark's findings, he is careful to point out, must not be given more statistical significance than they will bear, but they pave the way for extensive inquiries along the same lines

In England Now

A Running Commentary by Peripatetic Correspondents

THE story really started one afternoon in the early spring of 1941 In Sister C's off-duty time she was discovered digging a small parcel of ground outside the door of her ward—one of the many huts of our "up graded" hospital Soon, between some old apple trees, she had raked the surface to a fine tilth, and was busy sowing beans, shallots, peas, radishes and (with an eye to future ward decoration) clarkia, cornflower and other annuals Some superior people smiled, but when later on the results of her efforts appeared on the sisters' mess table at dinner she received much approval The beans tasted a treat This spring, one result of her pioneering was that several more sisters were smitten with the desire to *dig for victory* Trowels, *forks and spades* were purchased or borrowed, a convalescent patient—a gardener—was appointed acting unpaid consultant in horticulture, and soon evidence was to be seen of the enthusiastic labour that was going on The epidemic spread The office boys appeared with two sticks and a ball of string, the RMO and the steward presented blistered hands and were heard *to wonder whether* backache would respond to radiant heat, the almoner took a hand in staking a claim outside her sanctum, the X-ray department joined forces with the masseuse and even our *military* wing commandeered the ground around their sentry-box and sowed garden peas in mass formation Then a chance remark one evening bore fruit we must have a vegetable show in the summer

---

[1] From the Children's Nutrition Council 6, East Common, Harpenden (Herts) 1s

We discovered that among our latest joined housemen was one who had won prizes long ago in real horticultural shows. Moreover he has a flair for running things and knew just what was wanted, and so competition was stimulated and gardening almost ousted shop as the major topic of conversation at meal-times.

The great day arrived last Saturday. We had twenty classes: eighteen for vegetables, one for a bowl of wild flowers and one for the best arranged vase from a ward. The entrance fee was 3*d* for each entry, prizes were to be war-savings stamps. Each entry had two classes, the first was open to the produce from the gardens or allotments of any member of the hospital, the second was confined to produce from the hospital grounds. A panel of judges was formed by two friends in the neighbouring town, the lecture theatre was cleared and the exhibits placed on view. After the judging had been done the show was thrown open and the delighted prize-winners pocketed their stamps. One of the judges confessed that he wasn't quite satisfied with the award in the shallot entry, however the decision was confirmed when our oldest porter was heard to declare that the prize had been won by the firmest and most shapely shallots—"I reckon the judges couldn't 'a done otherwise." X ward sent a message to the kitchen yesterday: "Don't send any green vegetables today, we are going to eat our own."

* * *

It so happened that I entered my 70th year just as the world crashed into war. Naturally I wished to place such knowledge and experience as I had accumulated at my country's disposal, but wherever I applied I was made to realise with varying degrees of courtesy that I belonged to the past, for an epoch had suddenly closed. Whatever the future of medicine may be I shall be a stranger and have no part in it. I am forced to become a member of that lowest and most despised class—the rentiers. That is to say I am living on what I laboriously saved from years of practice and not on a pension provided by a grateful state. Already I seem to hear "definitely Edwardian—believes in evolution and the law of progress and won't realise that Marx and Engels enunciated the only true principles of science: quite moth eaten." I sometimes wonder, however, whether the "safety first" attitude of the planned future will quite compensate for the sense of adventure in the old days. Perhaps even that seems more pleasant in the retrospect than it did at the time. Anyhow, physicians will live differently in the future, even before the war the Harley Street district was becoming a hive of accommodation addresses. They will have the same experience as the Royal Academicians who no longer live in stately houses in Melbury Road or Grove End Road. The total sales at the Academy this year did not exceed the income of a single popular Victorian painter. Whether their art was worse than that of the present remains a moot point. Nevertheless "cheerfulness will keep breaking through," as I philosophically retreat into the background, where the past becomes more and more real, draws nearer and catches me up preparing to engulf me in it.

* * *

When Newton saw the apple drop, a sudden thought as light from Heaven. Bosh! The idea had been bobbing about in his head for years. Thought may sometimes be a reflex from outside, but one of that complexity must have been long woven in the fibre and pattern which is continuous from the baby's touch-taste thoughts to the dying man's frayed memories of his prime. It may have reached verbalisation point then, but far more probably Newton had to dramatise the whole affair to get his point over to others. In my insignificant sphere I can sense several natural laws but have not the mathematical ability to formulate them. There's Jones's Law, for instance. J used to be our bank manager—level-headed, safe, conventional, churchwarden, absolutely trustee stock. But when the blitz came he went all to bits and it then dawned on me that he had been walking on a tight-rope, he hadn't dared step off the straightline, that stiff conventionality was a protective mechanism, a path for a frightened soul, whereas our eccentrics have shown a great resilience to Fate's war-time rebuffs. Now I feel sure that this little truth could be suitably expressed in terms like the square of the conventionality is in inverse proportion to the coefficient of sanity. If I worked it out it would be sure to come out wrong, as my sums always did and I should as usual find that X equals Y—i.e., that eccentricity and sanity are equal, which is absurd, or isn't it? Then there's Brown's Law. Miss Brown gets a lot of pain for which I have never been able to find an anatomical basis. As a rule when patients use words like terrible, agony and writhe we conclude that they are trying to impress us rather than be strictly truthful, and Miss Brown is very lavish with such. Objective descriptions of pain have characteristics of their own, Osler's of his renal colic, and Ernest Waggett's of his endarteritis obliterans are good examples, they are meticulously boring like the golf bore's account of how he did the 5th in 4. Now the unit of pain is like the philosopher's stone, pharmacologists have tried to measure it by burning standard holes in their foreheads, schoolmasters in strokes of a cane, humorists in foot-pound hells (1 lb dropped on the foot from 1 ft), but they all come to grief because they are trying to measure two things—stimuli and receptivity. But here is a method that measures both together. Pain is in inverse proportion to the vividness of the description, or to the square root of the adjectives, or directly proportional to its boringness. Unfortunately another element of receptivity comes in, the listener's, for some people are more easily impressed or bored than others, and vary at different times of the day. Then again before one got one's formula one would have to apply a coefficient of taciturnity and verbosity and meiosis for each patient. On the whole perhaps we had better leave Brown's Law for a second Newton.

* * *

It fell to my lot a few weeks back to go down to the local station and meet the train bringing my daughter and elder son home for the holidays from their respective boarding-schools. The baby, of course, insisted on accompanying me, and the train was exactly an hour late. During that hour I was asked a vast number of technical questions about railways which I couldn't begin to answer, had to climb into various stationary and unclean trucks in sidings, explore and re-explore the "Gentlemen" and the small, bare waiting-room, cross the bridge over the line a dozen times, admire all the posters and hear their captions laboriously spelt out. When the train arrived at last it proved to be packed with supercilious-looking children of both sexes. My own pair, blinking owlishly in the corridor, evinced no disposition to get out until strongly exhorted by me to get a move on. When finally goaded to action they attempted to leave the train through a window. "Is this all the luggage?" I asked. "There ought to be a trunk somewhere," said my daughter vaguely. An obliging porter hastened towards the guard's van. "It *might* be up in front," she added as an afterthought. "All right," I said. "Hold on to the baby while I go and look." My elder son, carrying a bag in either hand and a tennis racquet between his teeth, began to follow me up the platform. "Don't follow me, you chump!" I yelled. "Stick those things in the car." The car was at the station gate in full view and not ten yards away. After a fruitless search the porter and I rejoined my daughter, who had, of course, let go of the baby. He, still thirsting for information, was lying prone on the platform with his head between the wheels and earnestly inspecting the underside of the train which was due to draw out at any moment. The trunk turned up on a later train and it was my privilege to go down and fetch it. Exponents of the boarding-school system of education stress the sturdy independence and self-reliance it teaches. I sometimes wonder. Insouciance would, I think, be a better word.

* * *

She is a shy middle-aged bespectacled spinster who keeps a wool-shop. To look at her you would say that her main interest in life was knitting. I was asked to see her because of a return of a tiresome blepharitis which she has had on and off for years. "I think it's all due to my hobby," she said. "Knitting?" I asked. "No-o," she laughed, "my real hobby—racing motoring. I used to do a lot of it at Brooklands and that's when it started." Life is full of surprises.

* * *

I was sitting in Christ Church meadows waiting for an exam—the very one in which we all slipped up about gangrene (*Lancet*, 1942, ii, 168)—and trying to read through my notes for the last time The mind is very divertable in such conditions, and it was not surprising that I started to notice the heifers They exhibited the girl-school mentality to a T At first they were crowded under one of the five possible trees where there was some shade, all milling around to get near the prefects in the middle Then some riotous girl set off for another tree, and at once, jumping and giggling, the whole herd streamed after her, unable to run without lifting their tails vertically into the air They crowded under this tree "Come on, Susan," said another heifer, "let's go off by ourselves"—and off went a white and a brown one, pursued by the whole boiling Three times they streamed round the whole vast extent of the meadows, tails in the air Susan, who was intelligent, knew it was a mistake, and turned to say so She saw the thundering herd, staggered, swung round, and galloped for her life As I got up to walk grimly to the Taylorian, they were still galloping, their tails still raised, a few dim-wits lumbering along behind without the least idea of purpose but determined, come what may, to go where Susan led

Letters to the Editor

DIAGNOSIS OF INTESTINAL INFECTIONS

SIR,—Flight-Lieutenant Vaughan's letter of Aug 29 (p 265) on the viability of the dysentery bacilli in fæcal specimens prompts us to submit a few germane observations We had already satisfied ourselves (Cruickshank, R and Swyer, R *Lancet*, 1940, ii, 803, Hynes, M *J Path Bact* 1942, **54**, 193) that the Sonne bacillus will survive for several days in fæces or rectal swab dipped in saline agar at atmospheric temperatures of 15–20° C In the spring of this year we had the chance to carry out similar tests on the viability of the reputedly more delicate Flexner bacillus Six positive fæcal specimens from different patients were kept on the bench (T 15–18° C) and plated daily on desoxycholate-citrate agar, in one the organism died out after 5 days, but in the remaining specimens the survival times were 8, 8, 15, 15, 15 days when further culture was stopped Similarly, five rectal swabs kept moist in saline agar were cultured daily, and the average survival time of the Flexner bacillus was 11 days Four positive fæcal specimens were divided, one portion being put in the incubator at 37° C and the other kept on the bench In each case, only scanty Flexner bacilli survived for 24 hours in the incubated specimens, whereas over 4 days the organism persisted in apparently undiminished numbers in the specimen at room temperature The pH of this material showed no obvious change in any specimen over 3 days

STERILISATION OF SULPHONAMIDES

SIR,—I was interested in your annotation of June 27 on the case of tetanus after local chemotherapy For the past year the problem of sterilisation of sulphonamide compounds for local use has been under consideration by the Committee on Chemotherapeutic and Other Agents of the National Research Council After a considerable amount of discussion, this committee decided to advise our armed forces and the Food and Drug Administration of the Federal Government that all sulphonamides which were to be used for topical application should be marketed in a sterile form We arrived at this decision largely on a theoretical basis, because up to the present time not a single case-report has appeared which suggested that the topical use of a sulphonamide compound was responsible for an ensuing infection

However, studies that had been made in this country showed that crystalline sulphonamides were occasionally contaminated with non-pathogenic spore-bearing and non-spore-bearing organisms It seemed to the committee that sulphonamide compounds might, under certain conditions, become contaminated with tetanus spores, and as it was well known that these compounds had but a minor prophylactic effect on experimental tetanus infections in mice it was decided that a recommendation should be made to the proper authorities concerning the necessity of the sterilisation of the sulphonamide compounds which were to be used for topical application

When this became known, various pharmaceutical manufacturers set to work in this country to devise methods for the proper sterilisation of crystalline sulphonamides I am enclosing a copy of a letter from Dr John H Brewer of Hynson, Westcott and Dunning, in which their method of sterilisation and control of crystalline sulphanilamide is outlined At the present time our Army and Navy are being supplied by Hynson, Westcott and Dunning with convenient 5 gramme packages of sterile sulphanilamide for topical use

Johns Hopkins University
School of Medicine

PERRIN H LONG

ENCLOSURE

The process we are now using for sterilisation is probably *much more than is necessary, but gives us a margin of safety* which is very desirable in these days of rushing things out to fill defence orders, &c We first became interested in the sterilisation of sulphanilamide when it was found that all the powder on the market from the various manufacturers contained bacteria of various kinds Many were contaminated with spore forming organisms and some were found to contain very resistant spore forming anaerobes After these findings were made we obtained the most heat resistant spore formers we could find—one strain of *Cl novyi* which the suture manufacturers use as a control organism and a strain of *Cl sporogenes* used by the canners as a control organism Most of the information in textbooks concerning the heat resistance of spores in hot air ovens was built up before the present accurate thermo electric instruments were available Since the temperature usually given for hot air sterilisation (160° C for one hour) is so near the melting point of sulphanilamide (163° C) we decided to restudy the resistance of some of the spores, making use of some of the more modern instruments with extended time as is practised by some canners It has been found that the most resistant spores of *Cl novyi* and *Cl sporogenes* can be killed at a temperature far below the melting point of sulphanilamide if the time element is extended sufficiently 130° C kills these organisms in four hours, but not in three, 140° C kills in three hours, but not in two, 150° C kills in two hours Various types of forced air ovens have been tried, both electric and gas The above temperatures will not hold for static ovens or ovens improperly baffled so that one obtains cold spots Our present technique is as follows

Spore controls are prepared by growing the organisms in cooked meat cultures for forty eight hours and storing the cooked meat culture for one month in the ice box The spores are then added to sulphanilamide and rotated in a ball mill to mix One gramme of the powder contains between 10,000 and 100,000 spores Five grammes of the powder is placed into control packages made from the same paper and prepared exactly as the finished package except it is printed in red with the words "Do Not Use Control Package" instead of the usual printing in black These control packages are tested for their heat resistance at least once each month So far we have found the heat resistance to *remain constant* Our present hot air oven which holds 50,000 packages each charge, so spaced in racks as to allow free circulation of the hot air, is loaded with control packages so that every cubic foot contains one control package The oven is routinely run at 145° C for four hours, which gives a margin of one hour and a 5° C temperature margin The oven is equipped with a thermocouple which can be placed directly in one of the packages and a recording thermostat for controlling the temperature and keeping a record on the run After the oven has cooled sufficiently the dollies are removed from the oven with the racks in place and the controls are removed and sterility tested

One fourth of each package (1 25 g roughly) is dusted into a tube of thioglycollate medium containing 2 mg of para aminobenzoic acid per 100 c cm This makes four tubes for each control package On each run several finished packages are also sterility tested This work is all done in dust free rooms to obviate contamination from the air which would hold up production The packages are quarantined in their original position in the oven dollies until a forty eight hour sterility packaging "OK" is given At this time if any controls have shown growth the trays which they control are resterilised Although we are having no difficulty now, before we got our technique working and before our oven was working properly we had many such instances In cases where contaminated controls have been found several hundred of the packages surrounding these controls have been tested and found to be sterile, showing that the organisms present in the sulphanilamide were not as resistant as our controls. However, at times we have isolated organisms equally resistant to *Cl. novyi* and *Cl. sporogenes* from several lots of sulphanilamide. The control tubes are incubated for seven days and a slipping "OK" is given.

Most of the other sulpha drugs have higher melting-points and do not offer the difficulties which sulphanilamide offers.

Professor Long also enclosed examples of the packages of crystalline sulphanilamide issued to the US Army and Navy. Each holds 5 g. The Army type consists of a stout paper envelope containing an inner sterile one perforated with holes at one end for use as a shaker. The holes are covered with a loose 'Cellophane' sleeve which is removed when the sulphanilamide is to be sprinkled on a wound. The directions say, "remove the sterile shaker package with sterile forceps." The Navy type is simpler—a cellophane envelope containing a sterile paper one, to be opened by tearing off the end. The Naval directions say, "After controlling hæmorrhage, sprinkle powder in wound, covering the depth and injured surfaces lightly; then cover with sterile dressing and bandage. Warning.—This drug to be used only as directed, using not more than two packets in wounds of one person."

MELORHEOSTOSIS

SIR,—Franklin and Matheson's description of their case, to which you refer in an annotation (Aug 22, p 224) confirms the view that Léri and Joanny's original description of melorheostosis as *hyperostose en coulée sur toute la longeur d'un membre* can no longer be accepted as adequate. Two years ago I described (*Quart J Med* 1940, 9, 1) some unusual bony lesions affecting the right hand of a boy suffering from tuberose sclerosis. This boy died eventually from the effects of raised intracranial pressure and fortunately I was able to secure a post-mortem investigation. My inquiry, details of which I hope to publish in due course, led me to the conclusion that melorheostosis represents a local disorder of osteogenesis in which a deficiency of the periosteum is associated with a characteristic hyperostosis to which the disorder owes its name.

Birmingham, 15. GILBERT S. HALL.

DYSPEPSIA IN SOLDIERS

SIR,—The paper by Dr Morton Gill and colleagues and the later correspondence raise many points of interest. The advantage of immediate admission of all dyspeptic soldiers and full investigation in a specialised unit must be weighed against certain drawbacks. Observation of a large number of such cases suggests that in many instances admission is directed purely towards the elimination of an inherently improbable organic disease. In such cases careful clinical diagnosis and disposal as an outpatient may be preferable, since inpatient observation, investigation and treatment are open to the risk of producing or increasing the patient's preoccupation with his digestion and so causing fixation of apprehensive attention upon his symptoms and his diet.

In soldiers it is difficult to exclude motivation of symptoms (unconscious or even conscious), and the will to recover is often less in evidence than in civilians earning their own living in a life to which they are more adapted. Such motivation probably accounts for the changes in symptoms often observed when questions of hospital admission or invaliding come to be mentioned. It is also noticeable that the relief of symptoms and response to treatment of peptic ulcer in soldiers is frequently much slower than in similar patients in peacetime, who were often relieved within a matter of a few days. This is the case even though in my experience soldiers with ulcer are as a rule of keen type, conscientious, anxious to do their bit and unwilling to blame the Army for their symptoms, which are usually of long standing. Even in these men, however, it will be important that their follow-up be observed after return to civilian life, since many show only little improvement after hospital treatment at the time of their discharge.

Among the large number of dyspeptics in whom, short of gastroscopy, no organic lesion can be found, general symptoms often outweigh and even antedate their digestive symptoms. When in such patients gastroscopic evidence of gastritis is found, it is difficult to attribute more than a part of their symptoms to this condition, especially since it is agreed that definite changes of gastritis may exist without symptoms at all. Failure of such cases to respond to treatment is suggested as a cause of their neurotic symptoms, but it seems that in some at least of these patients the organic gastric changes must be secondary to a primary neurosis, a sequence that is certainly understandable on clinical grounds. The extreme intolerance to anything but a special diet in gastritis is again regarded as indicative of a persisting gastric lesion; such dependence on a dietary regime may, however, be at least as often a mental state, and is indeed not infrequently suggested and implanted in the patient by his medical adviser. For this reason as much care is necessary in giving dietary advice to a dyspeptic as in advising restriction of exercise in cardiac cases.

Light diet and light duty are both expressions which well repay the most careful questioning, and their opposites—"heavy"—may also on inquiry offer illuminating insight into the nature of soldiers' dyspepsia. So many inconsistencies are apt to come to light that it becomes at once clear that the need for light diet or light work is psychological and not gastric; one case out of many may be given as an example of this.

A private, aged 29. Investigated and treated for 8 weeks, October–November, 1941, in special dyspepsia unit. Unit reports "no neurotic traits. Occult blood negative. Gastroscopy, œdematous hyperæmic mucosa with multiple erosions. Treated with bed and strict dieting for 6 weeks. Repeat gastroscopy shows gastritis to have healed, but there is residual stiffening of the mucosa *suggesting permanent* deep changes. Recommended he be posted to a unit where he has facilities for supplementing his diet, strictly avoiding all gastric stimulants and irritants. Recommendation—this patient is likely to relapse and if this occurs he should be boarded out of the Army without further investigations."

Seen by me on July 30, 1942. Since discharge from hospital has lived on special ration allowance at his own home. States he can only eat food cooked by his wife; complains of lack of energy, breathlessness, trembling, frightened when in buses, does not like the dark, fears "make his stomach turn." Such symptoms began suddenly with diarrhœa when he had a heavy job as a messenger boy aged 17, and he states that with their sudden onset he was afraid he would lose his job. On his mother's advice he had all his teeth out then, and has continued to treat himself with various medicines and diets ever since, without success. Carrying the post bag used to upset his stomach and any lifting or exertion still causes stomach pain.

Can only eat toast—without the crust. Boiled eggs cause heartburn and pain, but can eat them scrambled or poached. All potatoes cause pain except when mashed with milk and butter, when he can take them safely; cannot eat cheese or vegetables; can only take a little rice and occasionally turnip if sweet. A few mouthfuls of apple make him sick, and warm tea (*not* hot) burns him inside. Food makes him breathless and if he takes a bath he has to have the door and window open or he feels faint. States all these symptoms have persisted since the onset of his stomach trouble, age 17.

It must indeed be difficult for a soldier, after some weeks of hourly feeding and prolonged hospital dieting to regain confidence in his ability to eat ordinary food, and this must be even more difficult if he is warned to be continually careful of his food and that any return of symptoms is likely to lead to invaliding!

T. C. HUNT.

LIFE CYCLE OF THE THREADWORM

SIR,—It is perhaps somewhat presumptive, after twenty years of retirement, to enter the field of controversy in regard to the life history of *Oxyuris vermicularis*, but having in the past studied and treated large numbers of cases in native children in Malaya and Borneo I beg to record my observations in the hope of assisting in the treatment of these infestations.

My conviction is that the period occupied between the ingestion of the ova and the appearance of the fully developed female worms in the rectum may be, and generally is, only a matter of two or three days and not the two weeks so persistently stated in the textbooks. I was first convinced of this from the study of a Eurasian family in Taiping, Perak, FMS, about 1912. Three of the younger children were heavily infected, and as all of them were inveterate nail-biters there was, almost certainly, constant reinfection Two children of relatives (a boy and a girl) came to stay with the family for a holiday and each of them shared a bed with an infected child Neither of these children had, on arrival, any sign or symptom of infection, nor had they any previous history of having suffered from threadworms However on the third day one of these children had intense irritation at the anus and next day both of them showed numerous female worms in the stools, which had been preserved for my inspection, while microscopically ova were numerous in the fæces

Many will rush to their textbooks, where it is usually stated that the larvæ, after hatching, pass through two ecdyses before becoming mature, and that the duration of this cycle is two weeks Copulation takes place in the small intestine, after which the males apparently die out I suggest that this cycle may take place with far greater rapidity than has previously been thought possible

As regards treatment with drugs, past experience has not been encouraging, and when prevention of reinfection is undertaken with scrupulous care drugs of any kind are, in my opinion, unnecessary Ordinary purgation, combined with the application of an ointment of hydrarg ammon., with the addition of 5% menthol as a parasiticide and to allay irritation, generally brings about a complete cure in about a week 'Butolan' (Bayer), diphenan (BDH) and phenothiazine have lately been vaunted as cures, but I see already one death from the last named has been reported in the *Lancet* of July 11, 1942

Hove   WILLIAM BRYCE ORME

AUTUMN POLLEN FEVERS

SIR,—People over from Canada and the USA are frequently asking for, or at least about, protection from the autumn pollen-fever which produces so much distress and disability in North America The answer is that the causal plant—ambrosia ("ragweed")—doesn't exist here, there is therefore no need for protection in the autumn

This is not strictly true, there is a minor amount of trouble for some people from the pollen of our autumn composites, especially from the Michaelmas daisies which throng our gardens and are apt to fill our rooms at this time But this pollen can usually be dodged, for it is not nearly so ubiquitous as the grass pollen at midsummer Also it can be protected against by precisely the same inoculation technique as that employed so successfully against true hay-fever This is rarely necessary, I would put the ratio of the troubles from grass pollen (at midsummer) and from composite pollen (in the autumn) in the region of 100 to 5

There is also the trouble locally from heather pollen, but this is rarer still and seems to affect chiefly the plutocratic deer-stalker in peace-time Perhaps in war-time the soldier flat on his belly and creeping to an attack through heather may suddenly be overcome by sneezing, if thought worth while this also can be protected against prophylactically

Indigenous inhabitants have been asking for hay-fever prophylaxis for people going overseas It has to be explained that the timing, and even the need for protection, depends on where the man is going, it is hardly necessary outside the temperate zones where the grass grows richly, and then of course only at the local midsummer There is little or no hay-fever in the north of Africa where our men are fighting, and not very much in other tropical or subtropical regions where, if it occurs, it depends chiefly on the local rains

London W 1   JOHN FREEMAN

VESTED INTERESTS

SIR,—Your correspondent W. A G admits that "panel" practice, where doctors have had to pay for it, constitutes a vested interest with a right of compensation to the doctors if they do not continue in such practice because of government action—i e, it is the fact of purchase which gives the vested interest Doctors have originated the custom of buying and selling practices, not primarily, as W A G suggests, *for the support of medical agencies*, but agencies are frequently employed for convenience, and in order that practices may change hands in an ethical manner with due regard to the rights of both seller and purchaser Except for those squatters who have started in practice without purchasing from another doctor, and according to W A G may therefore have no claim to compensation for either private or panel, all practising doctors have purchased their panel and private work as a whole, and must surely be said to have an equal right of compensation for both parts The panel patient is no more a chattel to be sold or transferred against his will than is the private patient.

A J K D

MASS RADIOGRAPHY IN THE FACTORY

SIR,—Dr Stanford has done a good piece of work, and his success in persuading a number of workers to travel some distance to his X-ray apparatus is an achievement, but I feel he may be wrong about the capacity of his workpeople for understanding new ideas The 30 women in one of his shops who declined to work there after he had explained his scheme to them had obviously misunderstood him Their mistake may not have arisen simply because of the low "average mental level of the shop" I do not agree that the workers "hold the medical profession in profound suspicion", they may feel like that towards their employers, but I believe their tendency is to trust the doctor, perhaps expecting rather too much of him My own experience is that workpeople, particularly organised workpeople, quickly understand the advantages to them and the community of mass radiography, but almost as quickly perceive its implications And I agree with them that additional beds must be allocated, allowances for dependants should be made, and some sort of provision for graded return to work is needed, preferably on the lines of the recent memo of a committee of the Tuberculosis Association

Edgware   A STEPHEN HALL

Infectious Disease in England and Wales

WEEK ENDED AUG 29

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1455, whooping-cough, 1212, diphtheria 717, paratyphoid, 11, typhoid, 18, measles (excluding rubella), 3165, pneumonia (primary or influenzal), 352, puerperal pyrexia, 168, cerebrospinal fever, 66, poliomyelitis, 14, polio-encephalitis, 2, encephalitis lethargica, 3, dysentery, 91, ophthalmia neonatorum, 94 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Aug 26 was 1458, including scarlet fever, 313, diphtheria, 164, measles, 234, whooping cough, 243, enteritis, 51, chicken pox, 76, erysipelas, 44, mumps, 53, poliomyelitis, 1 dysentery, 24, cerebrospinal fever, 8, puerperal sepsis 29, enteric fevers, 7, german measles, 4, glandular fever, 1, malaria, 1, other diseases (non-infectious), 123, not yet diagnosed, 82

Deaths —In 126 great towns there were no deaths from scarlet fever, 2 (0) from enteric fevers, 2 (1) from measles, 9 (3) from whooping-cough, 16 (0) from diphtheria, 54 (4) *from diarrhœa and enteritis under two years*, and 11 (1) from influenza The figures in parentheses are those for London itself

Middlesbrough and Birmingham each reported 6 deaths from diarrhœa, Liverpool 5 and Manchester 4

The number of stillbirths notified during the week was 207 (corresponding to a rate of 34 per thousand *total* births), including 15 in London

---

MACHINE TOOLS OF MASS RADIOGRAPHY —The Minister of Health has appointed a central technical committee to *advise on the organisation of mass radiography* The new body will be a subcommittee of the minister's standing advisory committee on tuberculosis, and its members are chairman, Mr T Lindsay (Ministry of Health), Dr A E Barclay, Dr G Lissant Cox, Dr James Ferguson, Surgeon Commander W G C Fitzpatrick, Dr F R G Heaf, Dr George Jessel, Major Peter Kerley, Brigadier D B McGrigor, Dr S Cochrane Shanks, Dr Norman Smith, Wing Commander R R Trail, and Dr Harley Williams (secretary), with representatives of the Ministry of Labour and the Department of Health for Scotland The first sets of apparatus are expected to be available before the end of the year, and the remainder of the 25 already ordered will be in use during 1943 The committee intends to provide a scheme for the employment of these units throughout the country, including adequate technical standards It has already considered the training of personnel and the allocation of the first sets

Obituary

GERARD JOSEPH HANLY

MB NUI, FRCS, FRCSE

ACTING GROUP CAPTAIN RAF

Group-Captain Gerard Hanly, who died on active service on Aug 6 as the result of a flying accident qualified at the National University of Ireland in 1923 and was appointed to a commission in the medical branch of the Royal Air Force a year later During 1925–29 he served in India and on his return to this country at RAF hospitals at Halton and Cranwell He took the FRCSE and qualified as a pilot before he was posted in 1933 to Iraq for surgical duties He returned in 1936, and continued to fill specialist posts until again posted to Iraq in 1941 to command the hospital at Habbaniya.

Hanly was an able surgeon and an efficient and zealous officer, popular with his colleagues and his staff His interest in flying combined with his professional qualifications made him particularly suited to the care of RAF personnel and gave him an insight into the problems peculiar to the Service which lent weight to his advice

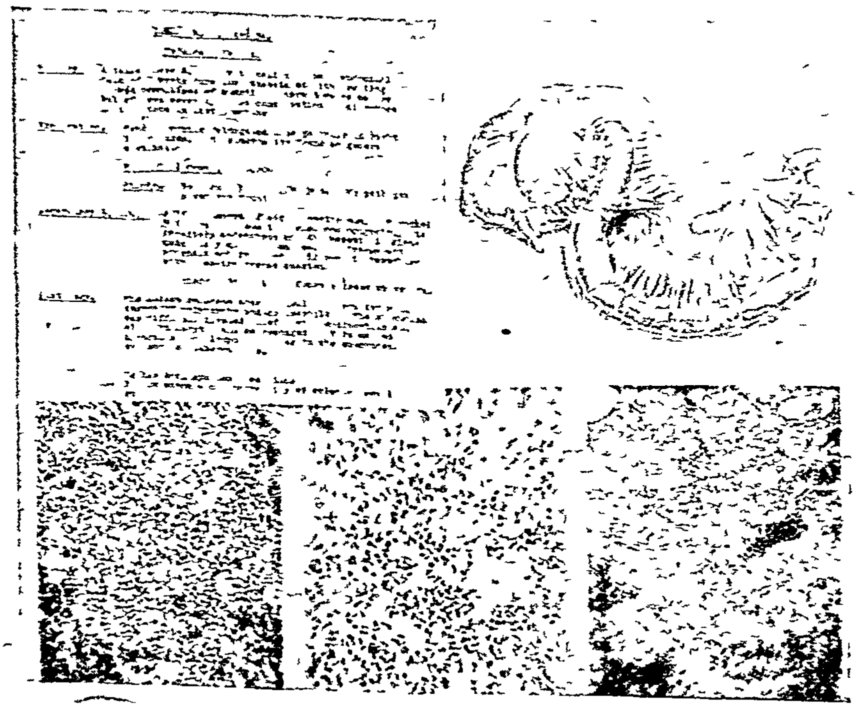
---

Surgeon Commander **James Michael McNamara**, RN who died from wounds last April, qualified MB from the National University of Ireland in 1923 He entered the Navy at the end of 1928 as a surgeon lieutenant for short service and transferred to the permanent list in 1932 Two years later he was promoted surgeon lieut - commander and he received his final rank in 1940 while serving on HMS *Hermes* He was forty years of age

Notes and News

PATHOLOGY IN PAINT

Hospital museums generally contain a few pots which provoke nothing but ribald guess-work and a good many more which give a thoroughly false impression of the lesion they are supposed to illustrate Nowadays it is increasingly difficult to get mounting and preserving materials for either operative or post-mortem specimens and the maintenance of natural colours is thus a temporarily lost art This has led the Middlesex county council to appoint Miss D H Barber who had already made drawings for the clinical staff as medical artist to the Central Middlesex County Hospital With the help of her careful and accurately coloured drawings, teaching cards like the one reproduced here can be made up A picture of the specimen in full colour is seen alongside microphotographs of its sections and a typewritten account of the case She is also able to make drawings of gastroscopic findings and extensive neuro-surgical operations which could not otherwise be reproduced These illustrations will be a valuable addition to the museum, and may in turn be accepted not merely as a substitute for other teaching material but as an advance



EYE INJURIES IN COALMINES

Ulcer of the cornea is common in the eye wards of the Edinburgh Royal Infirmary, and in a series of 350 ulcers 66 8% occurred in coalminers The condition is serious and the results of hospital treatment are poor Often no useful vision is left in the affected eye The average stay in hospital is about three weeks After two years' research work for the Ross Foundation for the Study of Prevention of Blindness in the pharmacology department of Edinburgh University it was discovered that 'Albucid soluble' is more effective in preventing infection of the cornea than any treatment previously used As the preparation is harmless to the eye it was felt that it could be confidently recommended as a useful first-aid treatment in ambulance rooms at collieries Thirty collieries in Scotland were selected for a trial of the new treatment and after six months the results have been summarised thus in a report issued by the foundation .

Total number of men employed at the collieries	23,500
Number of injuries treated with albucid soluble	646
Foreign bodies removed from the eye with brush	360

Of all cases treated at the ambulance room fifteen men lost 74 days' work, an average loss of 5 days Only seven cases were admitted to hospital with corneal ulcer during the six months and three of these had not had albucid treatment The length of stay in hospital varied from 19 days to 3½ months The success of albucid soluble in preventing infection and ulcer of the cornea has therefore been outstanding and the new treatment is greatly appreciated by workmen who regard it as a great improvement on the old The report has been brought to the notice of the Mines Department and the Factory Department of the Ministry of Labour and is obviously of wide general interest

THRASHING IT OUT

Since free speech is our birthright it is high time we learned to speak freely that seems to be the feeling which has moved the Association for Education in Citizenship to sponsor a series of handbooks for discussion groups under the ominous but stimulating title—taken from Mr Roosevelt—of *Unless We Plan Now*[1] The first four of the series are now available In the first Eva Hubback gives a thoroughly practical account of how to lead discussion groups, with suggestions for reading on modern political ideas, on governmental social and economic problems at home, in the Empire and abroad, international affairs, and psychology and clear thinking In the second handbook Francis Williams discusses the democratic idea Frank Hardie asks, in the third, "is Britain a democracy ?" He gives a concise picture of our electoral system and the structure of government The fourth, by Elizabeth E Halton, sets out some of the principles of planned housing under the title *Our Towns* The writers offer suggestions for reading, subjects for discussion, or lists of films and exhibitions bearing on their subjects Other handbooks in this series are to be on economic reconstruction, health, school education and schools, population and the cinema The association hopes in this way to encourage organised discussion of social, economic and political problems arising out of the war in such bodies as debating societies and discussion circles formed in the Forces, among civil defence workers, and in youth groups, church groups and women's societies

---

[1] Published for the Association by the English Universities Press Ltd St Hugh's School Bickley Kent 3*d* each

Nothing clears up the opinions of a woolly thinker so well as the discipline of making a speech about them , a clear thinker profits by what Prof R S Aitken has called the cross-fertilisation of other minds These handbooks carry the germ of plenty of lively thinking

University of Manchester

The degree of DSc in physiology has been conferred on Squadron-Leader Denis Williams, MD

University of Durham

Dr J C Spence has been appointed to a chair in child health at King's College, Newcastle on Tyne, which the university has created with the help of the Nuffield Trust

Dr Spence, who is 50 years of age, graduated with honours in medicine from the University of Durham in 1914 During that war he served with the 11th division in Gallipoli, Egypt and France After holding resident appointments at the Royal Victoria Infirmary and at Great Ormond Street he worked with the John and Temple research fellowship at St Thomas's Hospital, and later at the Johns Hopkins Hospital with a Rockefeller fellowship He returned to this country and to Newcastle, where he was clinical pathologist to the Royal Victoria Infirmary before being appointed to its staff and to the staffs of the Babies Hospital and the General Hospital He also became lecturer on diseases of children in the University of Durham He was one of the foundation members of the British Pædiatric Association and has been a keen critic of the education of medical students in child health Dr Spence took his MD in 1921, was elected FRCP in 1930, and his Bradshaw lectures to the Royal College of Physicians on the nature of disease in infancy were published in our columns (*Lancet*, 1941, i, 777)

Society of Apothecaries of London

At a court of assistants held on Aug 18, with Sir Stanley Woodwark, the master, presiding, it was resolved to revive the premedical examination in chemistry, physics and biology

The diploma of the society was granted to C A Anderson, R Powell, R Gunewardena, T W Renton, G Jarratt, P L McN Armstrong, A G S Bailey and F A Rutland

British Orthopædic Association

The annual general meeting of this society will be held at Nottingham on Sept 25 and 26 under the presidency of Mr G R Girdlestone On the morning of the 25th a clinical meeting will be held at the Harlow Wood Orthopædic Hospital, in the afternoon there will be a discussion on rehabilitation followed by a demonstration, at the Rehabilitation Centre for Miners, Berry Hill, near Mansfield On the 26th the meeting will be continued at the General Hospital, Nottingham

Industrial Health Research Board

The Medical Research Council have appointed the following to be members of their Industrial Health Research Board for the next three years Lord De La Warr (chairman) , Mr F C Bartlett, FRS, professor of psychology in the University of Cambridge , Brigadier General A C Baylay, Engineering and Allied Employers National Federation , Dr J C Bridge, senior medical inspector of factories , Dr A N Drury, FRS, Medical Research Council , Dr Thomas Ferguson, deputy chief MO of the Department of Health for Scotland , Dr M W Goldblatt, group MO of Imperial Chemical Industries at Manchester , Mr A Bradford Hill, DSc, reader in epidemiology and vital statistics in the University of London , Dr Donald Hunter, physician to the London Hospital , Dr Esther Killick, professor of physiology in the University of London , Air Vice Marshal Sir David Munro, chief MO at the Ministry of Supply , and Mr J L Smyth, general secretary of the Transport and General Workers' Union Prof A W M Ellis, FRCP, director of research in industrial medicine under the council, will also attend all meetings Dr R S F Schilling, one of H M medical inspectors of factories, has been seconded to the service of the council by the Ministry of Labour to act as secretary of the board The terms of reference of the board have recently been revised and are now as follows " To advise and assist the Medical Research Council in promoting scientific investigations into problems of health among workers, including occupational and environmental factors in the causation of ill health and disease, and the relation of methods and conditions of work to the functions and efficiency of body and mind , and in making known such results of these researches as are capable of useful application to practical needs "

Paddington Medical Society

This society will hold an informal reception at St Mary's Hospital, Paddington, on Sunday, Sept 20, at 2 30 PM, where members will meet medical men and women from America, the Dominions and India who are in this country on war service

Socialist Medical Association

On Wednesday, Sept 16, at 5 30 PM, Prof M Greenwood, FRS, will speak to this society on epidemiology and war On Wednesday, Oct 7, at 5 30 PM, Prof J A Ryle will discuss social medicine Both meetings will be held at the Conway Hall, Red Lion Square, London, WC1

Medical Casualties

The following RAMC officers have been posted as prisoners of war WS/Captain A M Boyd, MB Belf , Captain E T Gilbert, MB Belf , Captain W O James, MB Edin , WS/Captain A MacFarlane, MB , Major J Parkes, MRCP, WS/Captain E T M Smith, MB Birm , and T/Major A McL W Thomson, FRFPS

Survey of Scottish Hospitals

The Secretary of State for Scotland has appointed Prof J M Mackintosh, Prof C F W Illingworth and Dr R J Peters to investigate the accommodation, organisation, equipment, staffing, number and origin of patients treated in the general and special departments of West of Scotland hospital The survey, which may develop into a census of all Scottish hospitals, will be complementary to the work of the Hetherington Committee now inquiring into questions of principle likely to be involved in a large scale hospital reorganisation

STUDENTS GUIDE CORRIGENDUM —The regulations about submitting case-records and commentaries to the Royal College of Obstetricians and Gynæcologists apply to candidates for the Membership examination, not to those entering for the DRCOG as stated in our issue of Aug 29, p 247

Appointments

WILSON JOHN, MB RSO at the Montagu Hospital, Mexborough

MEYER —On Aug 30, at Exeter Charles Hartwig Louw Meyer, MD LOND, lieut colonel IMS retd , aged 82 years

NEFF —On Aug 28, at Nicosia, Eroll Aubrey Neff, CMG, MCPS Alberta, director of medical services Cyprus

WATERSTON —On Sept 4, in Edinburgh, David Waterston, MD EDIN, FRCSE FRSE aged 71

WOODROFFE —On Sept 3, in Bournemouth, Harry Dobrée Woodroffe MD DUBL

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

BRONCHIECTASIS WITHOUT DISABILITY

REPORT ON 25 CASES

L C MARTIN
M D CAMB, M R C P
PHYSICIAN TO THE EMS

F R BERRIDGE
M B CAMB, D M R
RADIOLOGIST TO THE EMS

RESEARCH ASSISTANTS IN THE DEPARTMENT OF MEDICINE,
CAMBRIDGE UNIVERSITY

UNTIL recently the term bronchiectasis brought to mind the picture of an ill patient with clubbed fingers, persistent cough, copious foul sputum and an ultimate death from toxæmia or cerebral abscess Apart from this classical picture there were cases of dry hæmorrhagic bronchiectasis, typified by repeated hæmoptyses and lack of other striking symptoms or physical signs (Pinchin and Morlock 1930, Moll 1932, Wall and Hoyle 1933) Only patients with these types of bronchiectasis appear in teaching hospitals and students remain unaware that bronchiectasis can exist without serious and spectacular symptoms—a condition termed simple bronchiectasis by Roles and Todd (1932) and described by Kerley (1934)

The objects of this paper are to describe 25 examples of bronchiectasis seen during 2 years in EMS hospitals among serving soldiers, most of whom were graded A1 in the Army, and to emphasise that even extensive bilateral disease can occur among men of healthy appearance and with little incapacity Many of the cases were detected as a direct result of the war and the facilities provided by the EMS for in peace-time few of the patients would have sought or gained admission to hospital The rigours of service life may have brought out symptoms which might otherwise have remained dormant for some time, and in the EMS hospitals concerned there were no outpatient clinics so that we had the advantage of investigating the men in the wards Most of the patients were admitted to hospital with acute bronchitis or other inflammatory chest episode, but in some the bronchiectasis was a chance finding after admission for some unrelated disease

The 25 cases were all soldiers who joined during the present war, except one who also served in 1914–18; 21 cases were between 19 and 29 years, the remaining ages being 32, 33, 33 and 52 years (see table) As civilians they had been artisans or manual workers, apart from 3 motor drivers, 2 clerks, 1 student and 1 male nurse

CLINICAL FINDINGS

Symptoms—Cough and sputum were presenting symptoms in 23 cases, dry pleurisy in 1 and evening pyrexia in 1 Subsidiary symptoms were dyspnœa and wheezing on exertion with recent lassitude or malaise in a few cases There was a history of hæmoptyses, all small, in 7 cases Apart from the case with dry pleurisy none of the men were incapacitated, and nearly all were grade A1 in the Army; those who were not had been downgraded for flat feet, poor vision or other extrapulmonary limitations Their state contrasts sharply with the distressing clinical pictures of bronchiectasis in textbooks

Cough was present in 23 cases for variable periods—under a month in 4 6–9 months in 4; 2–3 years in 2; and for many years in 13 cases In few was it constant and then not severe, being usual on rising, often attributed to smoking and generally regarded as not abnormal Few patients had sought medical advice in civilian life and only 2 had been X rayed (while in sanatoria suspected of phthisis) The cough was intermittent in most cases, and as a rule came on in winter after a sore throat, cold or chill Patients accepted the fact that they were chesty in the winter, but apart from full-blown attacks of bronchitis they rarely stayed away from work Sputum was produced by these 23 cases either constantly or intermittently according to the nature of their coughs, it was usually thick and yellow, never copious and only described as tasting nasty by 2 patients, 2 patients denied cough or sputum but one of them, admitted with a dry pleurisy, produced about an ounce of sputum daily Specimens obtained from 18 of the cases were all negative for tubercle bacilli

Of the 7 who had had hæmoptyses case 8 had had staining of sputum once 9 months before, case 9 had had two attacks, 9 months and 3 months before admission, case 11 had had two attacks, 3 months before admission and again while in hospital for treatment of varicose veins (this hæmoptysis led to examination of his chest), case 14 had had bloodstained sputum during an attack diagnosed as pneumonia a month before admission, case 20 had had hæmoptysis in 1900 during an attack of pleurisy; case 23 had had three attacks during the 18 months before admission (a typical case of dry hæmorrhagic bronchiectasis); case 24 had had hæmoptysis in 1941 during an attack of pleurisy

Nightsweats were reported in 6 cases, but were severe in none. Only 4 had lost weight, in the others the weight had risen or remained steady since joining the Army

Past history—There was a history of pneumonia in 13 cases In 10 of them this was during childhood or infancy; 2 had had several attacks In view of the clinical similarity between pneumonia, atelectasis and the many other inflammatory processes in childhood, a past history of "pneumonia" cannot be regarded as reliable There was a history of pleurisy in 8 cases and of bronchitis (in some several times or every winter) in 17. Whooping-cough was reported in 6 and measles in 8 cases during childhood Only 4 of the 25 cases gave no history of any significant chest disease Cases 13 and 19 had been in sanatoria in the past for suspected phthisis, cases 17, 19, 23 and 24 had been in military or EMS hospitals during the present war, yet in none had bronchiectasis been diagnosed This emphasises our point that bronchiectasis is still often unrecognised among patients who do not answer to the textbook descriptions

The exact part played by past chest diseases is difficult to assess when an established case of bronchiectasis is seen many years later. Pneumonia and atelectasis can both initiate bronchial dilatation if the affected lobe or lobes do not subsequently expand again properly, but

BRONCHIECTASIS IN 25 SERVICE PATIENTS

Case	Age	Past history	Type and distribution of bronchiectasis
1	33	Br often	Saccular, rt LL and ML (L lung not filled)
2	24	Pn as child pl 1940	Cylindrical rt LL, lt LL retrocardiac and ant basal bronchi
3	21	Br as child	Cylindrical; rt basal, lt. base normal
4	22	Pn twice as child, br twice	Fusiform lt post basal, rt. ant and post basal bronchi
5	29	Pn at 3 yr	Early cylindrical, lt. basal and rt ML
6	32	Pn at 18 yr, br often	Cylindrical, lt LL (rt LL normal)
7	25	Pn as child, br every winter	Saccular, rt ML and ant basal bronchus rt LL (lt lung normal)
8	21		Cylindrical lt post basal and retrocard bronchi (rt LL incompletely filled)
9	26	Br twice	Cylindrical lt LL (rt ML and LL normal)
10	28		Saccular, lt axillary basal and ant basal bronchi; few saccules in rt LL
11	26	Pl and pn at 7 yr, br twice	Cylindrical lt post basal bronchus (rt base not filled)
12	22	Pn at 5 yr and 3 times since pl at 20	Saccular, rt UL, ML and LL (lt lung normal)
13	20		Saccular rt. UL, ML and RL (lt. lung not filled)
14	20	Pn at 19	Cylindrical, lt ant., post and axillary basal bronchi, rt. retrocardiac bronchus
15	29		Saccular lt LL below 1st and 2nd dorsal bronchi (rt. base normal)
16	33	Br once	Cylindrical rt post basal bronchi (rt ML not filled lt LL normal)
17	19	Pl and pn at 19, br once	Cylindrical, rt post basal bronchi (lt base normal)
18	22	Pl at 22	Cylindrical rt retrocardiac bronchus
19	28	Br several times	Cylindrical, rt LL (lt LL not well shown)
20	52	Pl at 11 yr, br several times	Fusiform, lt LL (rt lung not filled)
21	22	Pn at 5 yr, br often	Early cylindrical, lt. LL and rt LL
22	28	Pl at 14, br once	Cylindrical lt LL and rt ML (rt LL normal)
23	26	Pn at 5, 7 and 11 yr; br often	Saccular, lt. LL (rt. LL normal)
24	41	Pn infancy, pl at 41 br several times	Saccular lt. UL and LL; rt. ML and LL
25	25	Pn and br. as child	Saccular, rt. UL, ML, and LL, lt UL

Br = bronchitis Pn = pneumonia. Pl. = pleurisy
UL = upper lobe ML = middle lobe LL = lower lobe

such inflammatory episodes repeatedly occur in a lung already the seat of bronchiectasis, so that one of them cannot be positively incriminated as the initiating factor unless the patient had had a previous bronchography The difficulty in stating the total duration of bronchiectasis in any of the cases in this series is thus evident If, however, the onset is held to date from one of the many chest diseases during childhood then the orthodox pessimistic outlook can hardly be maintained in view of the patients' present ages and military categories

Physical signs —Although some patients had bilateral bronchiectasis or considerable unilateral saccular disease none presented a toxæmic or ill-nourished appearance, 3 however were noted as undersize In 5 cases there was early clubbing of the fingers, amounting to shiny, rather curved nails with some loss of the crevice between finger and nail bed (as depicted by Lovibond 1938), only 1 example of gross or drumstick clubbing was seen This contrasts with the statement of Burrell (1936) that "clubbing of the fingers is almost always present in bronchiectasis," though he adds that "it is more marked in the toxic form"

Physical signs in the chest varied considerably in different patients and in the same patient from time to time *No abnormal physical signs could be elicited* from one patient who had had 2 small hæmoptyses and was found to be suffering from dry hæmorrhagic bronchiectasis *Impairment of percussion-note, diminished* air-entry, persistent coarse or medium râles and scattered rhonchi were commonly found in various combinations, while pleural friction was audible and palpable in 4 cases over the affected area of lung Bronchial breathing was rarely heard Of all physical signs impaired note, poor air entry and persistent râles were probably the most common.

The histories and symptoms of these cases, together with such physical signs made a diagnosis of bronchiectasis probable on clinical grounds alone and prompted bronchography, but exact interpretation of the physical signs by themselves in terms of partial collapse, pneumonitis or consolidation was impossible, and elucidation rested on radiological findings McGibbon and others (1939) found the same difficulty with physical signs in case of unresolved pneumonia and stressed the necessity for full radiological and bronchoscopic examination in such cases We were impressed by the similarities in history, symptoms and clinical signs existing between cases of chronic purulent bronchitis and true bronchiectasis, and although a plain radiogram often excluded the bronchiectasis we performed bronchography in doubtful cases As will be seen later bronchography alone is sometimes the sole means of differentiation between the two conditions

RADIOGRAPHY

Technique of bronchography —In the earlier cases of this series we used the technique of Franklin and Orley (1931) whereby iodised oil was injected through a rubber catheter passed through the nose into the larynx and trachea, after preliminary anæsthetisation with 5% cocaine hydrochloride This method gave excellent results but we later adopted the oral method described below because we found it quicker, simpler and less distressing to the patients Premedication with morphine, gr $\frac{1}{4}$, and atropine, gr $\frac{1}{150}$, was employed for patients with much bronchial secretion The throat and larynx were then anæsthetised with 5% cocaine hydrochloride from a de Vilbiss spray, which enables one to direct the *anæsthetic on to the larynx and epiglottis* The *tongue*, gripped in gauze, was then held firmly forward while warmed iodised oil ('Neohydriol' M&B) was injected straight on to the back of it from a 10 c cm 'record' syringe, fitted with a blunt ended filling needle about $2\frac{1}{2}$ in long and $\frac{1}{16}$ in in diameter No attempt was made to direct the iodised oil on to the larynx since with the tongue held firmly forward it collected in the closed pouch of the hypopharynx and spilled over into the trachea, in the manner described by Ellman (1939) Essential points in the technique are to use a de Vilbiss spray, to give the anæsthetic at least 10 min to act, to hold the tongue well forward all the time, and not to attempt to inject the oil on to the larynx If these instructions are observed oil will not pass into the œsophagus If the patient is placed in the appropriate posture any portion of the bronchial tree can be filled We have found that a 10 c cm record syringe is far easier to handle than the cumbersome syringes usually provided for introducing opaque oil This simple technique gave very good results, the use of a nasal catheter seems unnecessary, and the insertion of a needle through the cricothyroid membrane quite unjustifiable

The function of radiology in the diagnosis of bronchiectasis is to determine the presence of the disease, its character, and its extent These factors can all be accurately revealed by bronchography in the living subject, and by it alone The bronchographic appearances are characteristic and on the whole easy to interpret, the difficulty lies in the selection of cases for bronchography, the request for which is a joint decision of clinician and radiologist and not the responsibility of one alone

The saccular type of bronchiectasis can nearly always be detected on the straight radiogram Multiple cysts, usually accompanied by some degree of collapse and surrounding emphysema, are not likely to be confused with any disease other than a congenital cystic lung, which is regarded by some (Twining 1938) as essentially the same condition If there is partial collapse the affected lobe presents a honeycombed appearance, but in the presence of a complicating pneumonia or complete lobar collapse all trace of the cysts may disappear. There were 9 cases of saccular bronchiectasis in this series, and in only one, where the cystic area was obscured by the heart shadow, was the condition missed on the straight radiogram It is interesting to note the extent of saccular bronchiectasis which is compatible with apparently good health, for in 2 cases the whole of the right lung was involved and in 2 further cases all lobes except one of both lungs were affected In this type of bronchiectasis there is little difficulty in selecting cases for bronchography, for even if the disease is not evident on the straight film the presence of collapse is in itself an indication for this procedure

Cylindrical bronchiectasis and its more advanced "varicose" stage present a far more difficult problem The clinician and radiologist must strike a fine balance between over-anxiety, leading to the performance of many unnecessary bronchographies, and over confidence which allows bronchiectasis to pass unnoticed. Of the 16 cases of cylindrical bronchiectasis in this series, 4 were missed on the straight radiograms, bronchiectasis was suspected in 9 other cases but not confirmed by bronchography A further 16 bronchographies were performed on clinical grounds alone, unsupported by evidence from straight radiograms, and all these proved negative

We estimated that of every 5 bronchographies demanded by the clinician 4 were normal, and in only 1 had the radiologist missed bronchiectasis It is evident, therefore, that a fairly high standard of diagnostic accuracy is possible on straight radiograms alone, but bronchiectasis cannot be definitely excluded without bronchography While saccular bronchiectasis can be diagnosed on the straight radiogram by demonstration of the actual cysts, cylindrical disease is generally recognised by secondary changes in the bronchi and surrounding lung tissue, although the essential bronchial dilatation can sometimes be seen Cylindrical bronchiectasis, in striking contrast to the saccular type which may be extensive, is often confined to one or two bronchial divisions

Normal bronchi cannot usually be recognised beyond the hilar regions unless seen end-on, but they may occasionally be identified in the right cardiophrenic angle In many cases a large artery is seen in the outer part of the right cardiophrenic angle and its continuity can be traced with the vascular trunk at the hilum Just within, and running parallel to it, a large bronchus may be seen whose dilatation is a reliable sign of bronchiectasis. It is important not to confuse the pulmonary veins with the bronchi, the veins pursue a more oblique course upwards and inwards and their shadows are fainter than those of the arteries

Since bronchiectasis is so common in the right middle lobe and in the anterior and posterior basal bronchi, a full appreciation of the anatomical basis of the pulmonary markings in this area is essential The left cardiophrenic area is partially obscured by the heart shadow and it is in this region that bronchiectasis is most often overlooked Bronchial dilatation was confined to this area in 3 of the 4 cases which were missed on the straight radiogram in this series. Exaggeration of the bronchial markings, which makes their detection easier, is in itself a possible sign of cylindrical bronchiectasis, but as the appearance is due to fibrous or inflammatory thickening of the bronchial walls it is not pathognomonic nor an index of the extent of the disease. In some cases small areas of acinar collapse or consolidation occur round the affected bronchi, but this further stage in the inflammatory process, although more obvious, again is not pathognomonic of bronchiectasis. Crowding together and straightening of the bronchi are additional signs of bronchiectasis (Kerley 1938) and can be detected if the bronchial markings are exaggerated. It must be remembered, however, that for every bronchial shadow an arterial shadow is also visible and the crowding may thus be more apparent than real. Enlargement of the hilar shadows was not seen in these cases, possibly because of the low grade of infection present.

A combination of the appearances described suggested the diagnosis of bronchiectasis in 8 cases subsequently confirmed, but these signs also led to bronchography in other cases where no bronchiectasis was demonstrated.

Partial collapse of a lobe or segment of a lobe was present in 4 cases. Although Lee Lander and Davidson (1938) showed that the bronchi of a collapsed lobe were dilated in the presence of negative intrapleural pressure, slight lobar collapse is not always accompanied by bronchial dilatation. Compensatory emphysema develops peripheral to an area of collapse, and the resulting hypertranslucency is a useful sign when the collapse is not obvious (Twining 1938). Localised hypertranslucency of the lung can however appear on deep inspiration at one base without true emphysema; hence it is not conclusive evidence of collapse. Bronchiectasis was present in most of our cases without any accompanying emphysema, but true localised emphysema or collapse are both definite indications for bronchography.

On assembling the clinical and radiological findings, we can distinguish two groups of cases in which bronchography will almost certainly be normal:

1. Cases with pronounced bronchitis and copious sputum at the time of the straight X-ray examination, but showing either no radiological changes or only those of slight bronchial catarrh.

2. Cases which show greatly increased bronchial markings on the straight film but have no clinical findings or past history of chest disease to suggest bronchiectasis. Some other explanation of the radiographic findings must then be sought.

Little need be said of bronchographic appearances. In many of our cases the dilated bronchi extended well below the level of the dome of the diaphragm. Too much reliance must not be placed on absence of alveolar filling as a diagnostic sign of bronchiectasis, since this is often seen in asthmatics and may also be due to faulty posture at bronchography.

SINUS INFECTION IN BRONCHIECTASIS

The association of nasal sinus infection and bronchiectasis has often been noted in America during the last 20 years. Mullin (1921) showed that infection could spread from the nasopharynx and sinuses to the bronchi of rabbits either by direct aspiration or by lymphatics and blood-stream. In man, Quinn and Meyer (1929) and McLaurin (1932) demonstrated that iodised oil could be aspirated from the nares and antra to the bronchi, especially during sleep. It seems clear, therefore, that infected material can pass from infected sinuses to bronchi. The incidence of sinus infection in cases of bronchiectasis is about 70%, judged by findings in the 420 cases summarised below:

	Cases	Infected sinuses Cases	Infected sinuses %
Quinn and Meyer (1929)	38	22	58
Clerf (1934)	200		82
Hodge (1935)	37		75
Boyd (1935)	12	10	83
Goodale (1938)	75	46	61
Chipman and Collins (1939)	58	26	45

There have been many references to the improvement in cases of bronchitis and bronchiectasis after eradication of sinus infection, but no-one has *claimed that* sinus infection is an essential cause of bronchiectasis as distinct from a constant source of reinfection to already affected bronchi. Poorly developed sinuses or complete absence of the frontal sinuses have been described in bronchiectasis, and such congenital abnormalities at the upper end of the respiratory *tract* have been *hailed* as evidence of a congenital cause for the bronchiectasis. We found, however, that absence or poor development of the frontal sinuses was quite common in people with no chest disease.

Of the 25 cases of bronchiectasis the sinuses were X rayed in 17; they were clear in 10 and showed evidence of infection in 7. Of these 7, 6 had bilateral bronchiectasis and both maxillary antra were infected in 5—a finding in accord with that of Clerf (1937) who observed that bronchiectasis is usually bilateral when sinus infection exists. Of the 10 cases with radiologically normal sinuses, 7 had unilateral or unilobar bronchiectasis, and in only 3 was the disease bilateral. Thus the findings of Clerf (1927) and Goodale (1938) are again confirmed: the incidence of sinus infection is lower in cases of unilateral than bilateral bronchiectasis. Lack of radiological evidence does not, of course, preclude past sinus *infection*; some of our cases which gave a history of nasal catarrh had radiologically normal sinuses.

In a control series of 129 gastric cases, sinus infection was found in 56 (43·4%). Our series of bronchiectasis is too small for comparison, but if the control gastric series is compared with the 420 published cases of bronchiectasis quoted above it will be seen that sinus infection was found in approximately 70% of bronchiectasis cases as against 43% in the controls. We consider this to be supporting evidence of the common association of sinus infection and bronchiectasis, but no causal relationship between one condition and the other has yet been definitely established.

TREATMENT, DISPOSAL AND PROGNOSIS

Apart from instruction in postural drainage, and the treatment of infected nasal sinuses, these cases could not be further treated for bronchiectasis at the emergency hospitals in which they were seen. The men were clearly unfit for further military service and could hardly have been made fit for it by lobectomy or pneumonectomy at a thoracic centre; hence they were recommended for discharge from the Army, and in most cases this was effected. On their return to civil life full details were sent to their doctors, in whose hands the question of reference to a thoracic surgeon was left. Bilateral disease or other factors made 16 of the cases unsuitable for surgery. The remaining 9 cases *apparently* had unilobar disease (although the whole bronchial tree was not invariably outlined) and no doubt a lobectomy could have been done in some of these. Such treatment, in the long view, might be desirable in selected cases, but as Roles and Todd (1933) mentioned it is hard *to* advise a severe operation to a patient with little present disability and an uncertain prospect of developing any in the near *future*.

We cannot discuss the prognosis of our cases in particular, but the expectation of life for cases of bronchiectasis in general, as set out in previous papers, may be somewhat pessimistic. Some reports have evidently dealt with the relatively advanced cases seen in teaching hospitals, so that the survival-time after diagnosis bears little or no relation to the actual length of time the disease has existed. Thus Roles and Todd (1933) reported that 23 of 49 cases of bronchiectasis treated medically, were dead and 9 wholly incapacitated within six years of diagnosis. Warner (1935) estimated that 23% of 110 cases died after an average of nine years, while Cookson and Mason (1938) characterised bronchiectasis as a fatal disease. The difficulty in estimating the total duration of bronchiectasis has already been mentioned, but the significance of past chest disease, and of atelectasis in particular (Lee Lander and Davidson 1938), is now better recognised and should lead to earlier diagnosis.

Many of the patients in this series gave histories of chest diseases in childhood which might reasonably have initiated bronchiectasis, yet the men were still apparently fit enough 20 years later to be graded A1 in the Army and to have had little incapacity in civilian life. We do not know whether bronchiectasis of this type ultimately progresses to a fœtid stage with all the classical symptoms and signs, and it is possible that at least some of the patients might—save for bronchography—have passed such inflammatory episodes repeatedly occur in a lung already the seat of bronchiectasis, so that one of them cannot be positively incriminated as the initiating factor unless the patient had had a previous bronchography The difficulty in stating the total duration of bronchiectasis in any of the cases in this series is thus evident If, however, the onset is held to date from one of the many chest diseases during childhood then the orthodox pessimistic outlook can hardly be maintained in view of the patients' present ages and military categories

Physical signs —Although some patients had bilateral bronchiectasis or considerable unilateral saccular disease none presented a toxæmic or ill-nourished appearance, 3 however were noted as undersize In 5 cases there was early clubbing of the fingers, amounting to shiny, rather curved nails with some loss of the crevice between finger and nail bed (as depicted by Lovibond 1938), only 1 example of gross or drumstick clubbing was seen This contrasts with the statement of Burrell (1936) that "clubbing of the fingers is almost always present in bronchiectasis," though he adds that "it is more marked in the toxic form"

Physical signs in the chest varied considerably in different patients and in the same patient from time to time No abnormal physical signs could be elicited from one patient who had had 2 small hæmoptyses and was found to be suffering from dry hæmorrhagic bronchiectasis Impairment of percussion-note, diminished air-entry, persistent coarse or medium râles and scattered rhonchi were commonly found in various combinations, while pleural friction was audible and palpable in 4 cases over the affected area of lung Bronchial breathing was rarely heard Of all physical signs impaired note, poor air entry and persistent râles were probably the most common.

The histories and symptoms of these cases, together with such physical signs made a diagnosis of bronchiectasis probable on clinical grounds alone and prompted bronchography, but exact interpretation of the physical signs by themselves in terms of partial collapse, pneumonitis or consolidation was impossible, and elucidation rested on radiological findings McGibbon and others (1939) found the same difficulty with physical signs in case of unresolved pneumonia and stressed the necessity for full radiological and bronchoscopic examination in such cases We were impressed by the similarities in history, symptoms and clinical signs existing between cases of chronic purulent bronchitis and true bronchiectasis, and although a plain radiogram often excluded the bronchiectasis we performed bronchography in doubtful cases As will be seen later bronchography alone is sometimes the sole means of differentiation between the two conditions

RADIOGRAPHY

Technique of bronchography —In the earlier cases of this series we used the technique of Franklin and Orley (1931) whereby iodised oil was injected through a rubber catheter passed through the nose into the larynx and trachea, after preliminary anæsthetisation with 5% cocaine hydrochloride This method gave excellent results but we later adopted the oral method described below because we found it quicker, simpler and less distressing to the patients Premedication with morphine, gr $\frac{1}{4}$, and atropine, gr $\frac{1}{50}$, was employed for patients with much bronchial secretion The throat and larynx were then anæsthetised with 5% cocaine hydrochloride from a de Vilbiss spray, which enables one to direct the anæsthetic on to the larynx and epiglottis The tongue, gripped in gauze, was then held firmly forward while warmed iodised oil ('Neohydriol' M&B) was injected straight on to the back of it from a 10 c cm 'record' syringe, fitted with a blunt ended filling needle about $2\frac{1}{2}$ in long and $\frac{1}{16}$ in in diameter No attempt was made to direct the iodised oil on to the larynx since with the tongue held firmly forward it collected in the closed pouch of the hypopharynx and spilled over into the trachea, in the manner described by Ellman (1939) Essential points in the technique are to use a de Vilbiss spray, to give the anæsthetic at least 10 min to act, to hold the tongue well forward all the time, and not to attempt to inject the oil *on to the larynx* If these instructions are observed oil will not pass into the œsophagus If the patient is placed in the appropriate posture any portion of the bronchial tree can be filled We have found that a 10 c cm record syringe is far easier to handle than the cumbersome syringes usually provided for introducing opaque oil This simple technique gave very good results, the use of a nasal catheter seems unnecessary, and the insertion of a needle through the cricothyroid membrane quite unjustifiable

The function of radiology in the diagnosis of bronchiectasis is to determine the presence of the disease, its character, and its extent These factors can all be accurately revealed by bronchography in the living subject, and by it alone The bronchographic appearances are characteristic and on the whole easy to interpret, the difficulty lies in the selection of cases for bronchography, the request for which is a joint decision of clinician and radiologist and not the responsibility of one alone

The saccular type of bronchiectasis can nearly always be detected on the straight radiogram. Multiple cysts, usually accompanied by some degree of collapse and surrounding emphysema, are not likely to be confused with any disease other than a congenital cystic lung, which is regarded by some (Twining 1938) as essentially the same condition If there is partial collapse the affected lobe presents a honeycombed appearance, but in the presence of a complicating pneumonia or complete lobar collapse all trace of the cysts may disappear There were 9 cases of saccular bronchiectasis in this series, and in only one, where the cystic area was obscured by the heart shadow, was the condition missed on the straight radiogram It is interesting to note the extent of saccular bronchiectasis which is compatible with apparently good health, for in 2 cases the whole of the right lung was involved and in 2 further cases all lobes except one of both lungs were affected In this type of bronchiectasis there is little difficulty in selecting cases for bronchography, for even if the disease is not evident on the straight film the presence of collapse is in itself an indication for this procedure

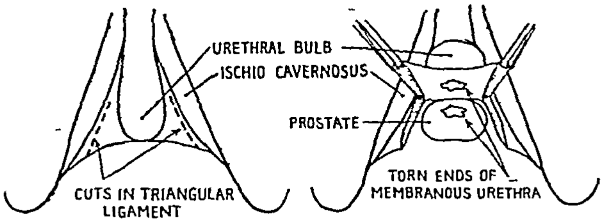
Cylindrical bronchiectasis and its more advanced "varicose" stage present a far more difficult problem. The clinician and radiologist must strike a fine balance between over-anxiety, leading to the performance of many unnecessary bronchographies, and over confidence which allows bronchiectasis to pass unnoticed Of the 16 cases of cylindrical bronchiectasis in this series, 4 were missed on the straight radiograms, bronchiectasis was suspected in 9 other cases but not confirmed by bronchography A further 16 bronchographies were performed on clinical grounds alone, unsupported by evidence from straight radiograms, and all these proved negative

We estimated that of every 5 bronchographies demanded by the clinician 4 were normal, and in only 1 had the radiologist missed bronchiectasis It is evident, therefore, that a fairly high standard of diagnostic accuracy is possible on straight radiograms alone, but bronchiectasis cannot be definitely excluded without bronchography While saccular bronchiectasis can be diagnosed on the straight radiogram by demonstration of the actual cysts, cylindrical disease is generally recognised by secondary changes in the bronchi and surrounding lung tissue, although the essential bronchial dilatation can sometimes be seen Cylindrical bronchiectasis, in striking contrast to the saccular type which may be extensive, is often confined to one or two bronchial divisions

Normal bronchi cannot usually be recognised beyond the hilar regions unless seen end-on, but they may occasionally be identified in the right cardiophrenic angle In many cases a large artery is seen in the outer part of the right cardiophrenic angle and its continuity can be traced with the vascular trunk at the hilum Just within, and running parallel to it, a large bronchus may be seen whose dilatation is a reliable sign of bronchiectasis It is important not to confuse the pulmonary veins with the bronchi, the veins pursue a more oblique course upwards and inwards and their shadows are fainter than those of the arteries

Since bronchiectasis is so common in the right middle lobe and in the anterior and posterior basal bronchi, a full appreciation of the anatomical basis of the pulmonary markings in this area is essential The left cardiophrenic area is partially obscured by the heart shadow and it is in this region that bronchiectasis is most often overlooked Bronchial dilatation was confined to this area in 3 of the 4 cases which were missed on the straight radiogram in then removed The remaining six sutures were inserted and tied in pairs, the perineal structures being gradually hinged back to their normal positions During the whole of this process the prostate had been pressed down towards the perineum As the anastomosis was completed, the penile catheter was removed

The abdominal and perineal wounds were then closed The bladder was drained by a de Pezzer catheter, and a rubber tube was inserted into the cave of Retzius In the perineum, absolute hæmostasis was secured and the divided structures loosely resutured The incision was completely closed, except for a small piece of corrugated rubber inserted into the subcutaneous layer



Exposure of ruptured membranous urethra

The patient was transfused with three pints of stored blood during the operation and returned to the ward in excellent condition, T 99 5° F, P 95 and R 20 The pelvis was supported with a binder

POSTOPERATIVE COURSE

The patient progressed well, considering the severity of the injury and the extent of the operation There was never cause for anxiety Sulphanilamide was given by mouth, 4 g on the day of the accident, then 5 g daily for three days and then 3 g daily for a further five days The perineal drain was removed on the third day, the wound being dressed with sulphanilamide powder to minimise the risk of introducing infection There was never more than a scanty discharge of blood stained serum and this wound did not become infected Bladder irrigations through the de Pezzer catheter were begun on the seventh day on account of a minor urinary infection The tube draining the cave of Retzius was removed on the eighth day and the stitches of both wounds on the tenth On the fifteenth day the de Pezzer catheter was removed and the urine drained off by suction on an Irving's box On the seventeenth day unsuccessful attempts were made to pass a soft rubber catheter and a Liston sound On the nineteenth day an anæsthetic was given and a no 7 (English) " coude " catheter was passed without obstruction It was tied in for 48 hours with a Duke's apparatus attached The bladder was irrigated every two hours, using boracic lotion Exactly three weeks after the accident the suprapubic wound had closed, and on removal of the penile catheter the patient passed urine naturally and without undue discomfort A sterile specimen taken next day showed the urine to be almost clear, containing but a few pus cells and a little amorphous debris Culture resulted in a very scanty growth of coliform organisms For the next fortnight micturition occurred about two hourly by day and four hourly by night, after that it rapidly settled to normal It has never been necessary to dilate the urethra Gum-elastic bougies have been passed five times, 1, 2, 3, 6 and 15 months after the accident, and their passage has never met with any resistance or resulted in hæmorrhage The largest size passed on each occasion was either a no 13 or a no 14 (English) The external meatus would not admit a size 15 bougie without causing undue pain The pelvic fracture united well For the first three days the pelvis was supported by a simple binder, and then, for five weeks, by a counterbalanced pelvic sling arranged to exert slight compression on the pelvis By the middle of March there was but little limitation of adduction and abduction at the left hip joint, and other movements were full and painless On April 3 the patient walked with crutches without putting his left foot to the ground On April 18, twelve weeks after the accident, he discarded the crutches He walked without pain or limp He returned to work seven months after the accident

He was last seen on April 9, 1942, nearly fifteen months after the accident He was in perfect health and doing heavy work Micturition and sexual functions were normal There was no physical disability Urethral instrumentation showed that there was no stricture

DISCUSSION

These patients are badly shocked, having usually sustained a severe compression or impact injury Treatment of the shock must be thorough and effective to justify the additional risks pertaining to the relatively extensive and long operation for primary repair of the urethra The prospect of a probable reduction in the incidence of stricture formation surely justifies these risks The arrangements in the operating-theatre must be planned and the patient prepared so that two surgeons can operate concurrently yet independently The time taken over the operation is thereby considerably reduced, with corresponding benefit to the patient Care must be taken to ensure that the theatre is well warmed and that as little as possible of the patient is exposed, since the lithotomy-Trendelenburg position spreadeagles the patient more than is desirable

The division of the attachments of the triangular ligament to the ischio-pubic rami allows mobilisation of the membranous urethra (see figure) The cuts in the triangular ligament are short, extended only until the distal end of the torn urethra is just seen when the central part of the triangular ligament is hinged forwards, carrying the bulb with it In this procedure there is a risk of dividing branches of the superficial perineal nerve and artery and of the nerve and artery to the bulb, but it appears from the above case that no permanent damage is sustained Gentle manipulation of the base of the bladder from above enables the torn ends of the urethra to be opposed and sutured The tear, in contrast to ruptures in the bulbous urethra, is usually clean and the anastomosis correspondingly exact Drainage of the perineal wound is therefore unnecessary

A temporary suprapubic cystotomy should be performed in all cases of ruptured membranous urethra, as emphasised by Girling Ball (1938) It is an indispensable step in the operation if primary anastomosis without an indwelling catheter is to be carried out The suprapubic tube should not be removed until the urethra has been given time to heal In the case reported a penile catheter had to be inserted on the nineteenth day for two days before urine would pass naturally In the absence of a stricture, the suprapubic wound may be expected to heal immediately

Infection is the greatest obstacle in all these cases If torn tissues are accurately opposed and infection suppressed a satisfactory result may be anticipated The administration of a sulphonamide compound is therefore obviously desirable In the case recorded, sulphanilamide was administered from the beginning by mouth and the urinary infection was minimal The perineal wound was dressed with the powder and did not become infected

SUMMARY

A case of ruptured membranous urethra is described in which the tear in the urethra was repaired by primary end-to-end anastomosis without an indwelling catheter Suprapubic cystotomy was done Infection was minimised by the administration of sulphanilamide All wounds were healed within three weeks Fifteen months after the accident there is no stricture

SCHOOL MEDICAL SERVICE ECONOMIES—The Board of Education have again asked local authorities to review their school medical services with a view to securing the most economical use of their staffs The board regard as essential the medical examination of children on admission to school and again in their last year of school life, but they are willing for the examination of the intermediate age group to be temporarily discontinued This arrangement will throw fresh responsibilities on the school nurses who have to keep a vigilant eye on the unexamined children, and the board are anxious that trained women shall no longer be used for such duties as examining the children's heads for nits or as dental attendants through life with no more serious diagnosis than chronic bronchitis A follow-up study of such cases can alone settle the question , but we believe that earlier diagnosis of bronchiectasis will show that the more familiar termination of the disease is not so inevitable as has hitherto been held

SUMMARY

Of 25 cases of bronchiectasis in serving soldiers, most gave a history of pneumonia or other chest disease in early life

Physical signs alone often failed to distinguish between true bronchiectasis and chronic purulent bronchitis Straight radiograms by themselves enabled bronchiectasis to be definitely diagnosed in some cases and suspected or excluded in others Bronchography was essential for demonstrating the exact extent of the disease, even when recognised in the straight film, and for proving the presence or absence of bronchiectasis in doubtful cases

An oral technique for bronchography was preferred to nasal or intratracheal techniques

Bronchiectasis, sometimes gross, was found to be fairly common in patients of apparently healthy appearance and little physical incapacity Such patients are rarely seen in general hospitals in peace-time Their expectation of life may be less gloomy than has been generally assumed

We wish to thank Dr H B Padwick for the use of the X ray films in one case , Dr W Paton Philip, tuberculosis officer for Cambridgeshire, for wise counsel , and Prof J A Ryle for criticism and advice

COMPLETE RUPTURE OF THE MEMBRANOUS URETHRA

TREATED BY ANASTOMOSIS WITHOUT AN INDWELLING URETHRAL CATHETER

ALAN H HUNT
D M OXFD, F R C S
TEMPORARY ASSISTANT SURGEON AND EMS SURGEON,
ST BARTHOLOMEW'S HOSPITAL

C NAUNTON MORGAN
F R C S
LIEUT COLONEL R A M C
ASSISTANT SURGEON TO THE HOSPITAL

THE aim in treating a ruptured urethra is to restore continuity without producing a stricture To achieve this result, it is necessary to abide by certain principles

1 To operate as soon as the patient's general condition will allow before the traumatised tissues have become œdematous before extravasation of urine has occurred and before the site of the rupture has become infected The patient is told not to attempt to pass water and is given a sedative It may be necessary to carry out a suprapubic puncture if operation is unavoidably delayed

2 To approximate the torn ends as accurately as possible

3 To prevent urine from passing over the healing wound by suprapubic drainage or proximal catheterisation through undamaged urethra

4 To avoid using an indwelling catheter until healing is complete, Foreign material within the urethra predisposes to infection, and seepage of urine will occur alongside an indwelling catheter even if the main flow is short circuited

5 To minimise the risk of infection by scrupulous asepsis, absolute hæmostasis and the obliteration of dead spaces

6 Later, to avoid the frequent passage of unnecessarily large instruments which would damage the recently healed urethra

When the bulbous urethra is torn, these principles (adapted from Grey Turner 1923) can usually be applied conscientiously The rupture is of easy access and the urine can be successfully short-circuited On the other hand, technical difficulties encourage an exception to be made in cases of rupture of the membranous urethra The torn ends are usually approximated by means of *special indwelling catheters (Harrison 1941)*. The use of these catheters has even been justified by the supposition that "the membranous urethra, unlike the bulbous, shows very little tendency to stricture formation " (Hamilton Bailey 1927–28), a belief not always shared by those who have to carry out the perennial or biannual dilatations necessary in many of these cases However, it is possible to expose the junction of the prostatic urethra and membranous urethra by dividing the lateral attachments of the triangular ligament and hinging the flap thus constructed forwards into the perineal wound On this principle we devised an operation which was carried out in the following case

CASE-REPORT

A post office jointer, aged 24, sustained a comminuted fracture of the pelvis and a complete rupture of the membranous urethra on Jan 26, *1941* A bus skidded into a bomb crater in which he was working, and pinned him down on his right side One of the front wheels crushed in the left side of his pelvis and came to rest on the upper part of his left thigh He was admitted to St Bartholomew's Hospital in a state of great shock There were fractures of both left pubic rami and the acetabulum, which had been driven about 1 cm into the pelvis Blood oozed from the external urinary meatus A tender abdominal swelling developed, rising out of the pelvis, and a hæmatoma appeared in the perineum Operation was carried out four hours after admission, as soon as the patient was sufficiently recovered from the shock

OPERATION

The patient was placed in the lithotomy Trendelenburg position as described by Lloyd Davies (1939), with the hypogastrium, genitalia and the anterior half of the perineum *prepared for operation and isolated as one site*

Abdominal surgeon —A large pelvic hæmatoma was evacuated through a midline suprapubic incision The bladder was partially distended and its wall suffused with blood but not torn The prostate was entirely separate from the triangular ligament, indicating a complete rupture of the membranous urethra A jagged spicule of bone projecting inwards from the left ilio pubic ramus was removed The bladder was opened and a Liston sound was passed in a retrograde direction through the prostatic urethra into the hæmatoma, which was temporarily packed with gauze

Perineal surgeon —A large soft rubber catheter could only be passed 20 cm up to the rupture in the urethra A transverse incision was made just behind the urethral bulb and deepened to expose the tips of the soft rubber catheter and the sound in the hæmatoma The left half of the triangular ligament had been torn free from the fractured pubis at the accident The right half was divided by a cut extending from behind forwards and inwards between the ischio cavernosus and the bulbo cavernosus muscles (see figure) The central part of the triangular ligament was thus left attached only anteriorly, hinged so that its upper abdominal surface could easily be brought into view

Both surgeons —The abdominal surgeon then removed the packing which had been introduced temporarily to allay hæmorrhage and pressed the base of the bladder firmly but *gently down towards the perineum* Using the rubber catheter and the sound as guides, both ends of the torn urethra could be found and approximated by the perineal surgeon An end to end anastomosis was done with nine interrupted fine plain catgut sutures on an atraumatic needle, introduced so that the knots were outside the lumen The three deepest sutures were introduced first, with the triangular ligament hinged forwards, and the guiding instruments withdrawn so *that only* their tips showed The sound was cytosis has been the usual finding Differential white counts in 10 cases showed normal relationship between myeloid and lymphoid cells Multilobed polymorphs exceeded earlier types

Sternal puncture was performed on 6 of our cases, and the findings are given in table I

TABLE I—DIFFERENTIAL OF MARROW CELLS (% OF TOTAL NUCLEATED CELLS)

Case no	7	9	10	15	17
Hæmoglobinised megaloblasts	3	1	0	0	0
Basophilic megaloblasts	16	14	3	4	4
Erythroblasts	4	18	19	20	10 5
Normoblasts	26	4	4	14	20
Total nucleated red cell types	49	37	26	38	34 5
Myeloid leucocytes		49	47	55	58 5
Total leucocytes	39	53	57	59	65 5
Degenerate or unidentified cells	12	10	17	3	0

A full differential count was not performed in case 6 but the ratio of red to white cells was 6 4 with normoblasts showing a well-marked preponderance

TREATMENT

The disease is subject to natural remission at the end of pregnancy so that evaluation of treatment is impossible unless a control period is allowed for spontaneous improvement keeping the patient on a diet poor in the natural sources of extrinsic factor This is often impracticable because many of the patients are dangerously ill on admission to hospital and immediate treatment becomes a necessary life-saving measure If the patient has had a poor diet throughout pregnancy, and especially if a test-meal shows a normal amount of free hydrochloric acid in the gastric juice, lack of extrinsic factor alone may be the cause of the anæmia, and the addition of marmite in ½ oz doses daily to a good mixed diet may produce the desired response We found that marmite was poorly tolerated and often had to be discontinued owing to nausea and vomiting If marmite fails, or the above specified conditions are not present, a pure liver extract such as anahæmin, in doses of 5 c cm intramuscularly every four days, should be given and the response observed We have found that several cases which failed to respond to such measures rapidly improved if comparable doses of a crude extract such as campolon, were given furthermore, cases which failed to respond to either refined or crude extracts showed immediate and dramatic improvement if given ½ lb of raw or lightly cooked liver daily We do not consider that the iron contained in such quantities of liver could produce such an immediate response, and ascribe its potency to a hæmopoietic factor which is lost in the process of extraction

Blood-transfusion should be given only when the hæmoglobin level becomes desperately low It has no specific hæmopoietic property but is fairly well tolerated, it proved a valuable temporary measure in 9 of our 23 cases

The criteria we used to constitute a response were these (1) Subjective sensation of improvement by the

TABLE II—RESPONSE TO TREATMENT

Case	Treatment group	Hb % on admission	Weeks in hospital	Hb % on discharge	Treatment after discharge	Follow up		Remarks
						Time interval	Hb %	
1	1	49	3	67	Occasional iron	4 mth	81	Spontaneous remission
2	1	54	2	74	Nil	6 mth	90	Had iron before admission
3	2	35	4	52	Nil	4½ yr	106	15 days on controlled diet, then response to marmite
4	,,	35	1	48	No record	5 days	54	Campolon 5 c cm on discharge
5	,,	52	2	58	'Campolon' 5 c cm per month	16 mth	88	At first improved on normal diet later needed crude extract
6	,,	39	4	60	Iron	1 yr	95	Now cannot tolerate iron , Hb falling with low C I
7	,,	16	4	63	Nil	18 mth	94	Transfusion 1 pint and 10 c cm pure extract no response , then vit B rich diet, immediate improvement
8		17	3	53	'Marmite'	2 mth	72	Transfusion 1 pint then marmite
9	3	26	3	58	Iron	9 mth	89	Hb stationary for control period then rose with 10 c cm anahæmin — iron
10		22	5	67	Anahæmin for 1 yr , then iron only	2 yr	80	Transfusion 22 oz
11	4	15	3	46	One dose 5 c cm campolon	6 mth	67	52 % reticulocytosis
12	,,	17	4	60	Nil	10 mth	79	One injection only 5 c cm
13	,,	28	3	47	Nil	5 yr	100	15 c cm crude extract in hospital
14		12	5	40	Iron only	3 yr	87	Transfusion 3½ oz
15	,,	12	5	47	Occasional iron	3 yr	100	Transfusion 1 pint 10 c cm crude extract
16	,,	16	4	52	Anahæmin 5 c cm per fortnight 5 doses , also campolon	5 yr	63	Low CI but cannot tolerate iron Subsequent normal pregnancy anæmia being forestalled by campolon 5 c cm twice weekly
17	,,	19	3	48	No record			5 pints blood prior to D & C
18		9	4	50	Raw liver and 'Bemax	1 mth	80	2½ pints of blood — pure extract no response , crude extract + raw liver, 33 % retics
19	5	25	4	60	Raw liver	10 days	81	1 pint blood then ½ lb liver daily
20	,,	33	3	48	No record			20 c cm crude extract Hb 32–29 % , rapid response to liver
21		15	5	62	Liver unobtainable, so campolon 5 c cm per fortnight	2 mth	76	No response to extracts
22	,,	25	6	56	Marmite	7 mth	90	Hb fell to 19 % with 9 oz blood + crude extract 35 % reticulocytosis to raw liver
23		17	3	46		Still in hospital		Hb fell to 11 % with pure extract cells of 1 pint of blood + raw liver, 34 % reticulocytes

PERNICIOUS ANÆMIA OF PREGNANCY

A STUDY OF 23 CASES

H G MILLER
M D DURH, M R C P

T C STUDDERT
M B DURH

(*Department of Medicine, King's College and the Royal Victoria Infirmary, Newcastle on Tyne*)

ALTHOUGH pernicious anæmia of pregnancy was first described by Osler[1] in 1919 and is the subject of an excellent review by Stevenson,[2] textbooks of medicine continue to give unsatisfactory and even contradictory accounts of the disease We here report 23 cases, seen in this hospital during the last five years Few of them were suspected by the outside doctors, and in many cases the patient was permitted to become dangerously ill before investigation and treatment were carried out The disease is a macrocytic hyperchromic anæmia occurring late in pregnancy or in the puerperium It differs from pernicious anæmia in that there is not necessarily achlorhydria, the prognosis for complete cure is better, and subacute combined degeneration does not occur

ANALYSIS OF CASES

In this analysis 3 doubtful cases (one of which died) have been excluded

Age —Range 22–41 yr , average 31 , 18 out of 23 were under 35 yr During the same period of five years 222 females with true pernicious anæmia were admitted to the ward , their ages ranged from 16 to 77, and only 12 were under 35 yr Three pernicious anæmia patients became pregnant, and the doses of liver extract had to be increased to an average of 5 c cm per week to keep their blood at satisfactory levels Two had full term, normal deliveries, the third is now 6 months pregnant It should be noted that patients with uncomplicated pernicious anæmia are not normally admitted from the outpatient department unless the anæmia is severe

Parity —Four cases were seen in primiparæ, and one was an 11-para Average parity was 4 One case subsequently became pregnant again 3½ years after the attack, but recurrence of symptoms was forestalled and the hæmoglobin kept above 60% by intramuscular 'Campolon' therapy throughout pregnancy In 20 cases the infants were healthy , 2 cases were associated with stillbirth, and one with twins In one case the child showed moderate non-deficiency anæmia (Hb 64% with colour-index 0 73), but no abnormality was found in other cases where the child's blood was examined

Family history —One case had a sister with true pernicious anæmia , 5 cases had vague family history of "anæmia"

Past history of "anæmia" was vague and unsatisfactory but considered relevant in 5 cases

Diet —All the cases recorded are of "hospital" class, many from poor surroundings Of the 19 with a proper dietary history, 7 had gross deficiency of both protein and vitamin content Of the 12 cases in which the diet appeared to have been adequate, vomiting was severe and long-continued in 7 , 4 of the remaining 5 cases in this group had an excellent dietary history and no apparent digestive upset or failure of absorption One factor in some cases was that, as œdema and vomiting were frequent early symptoms of the disease, this was aggravated by the imposition of a protein-free diet for supposed toxæmia A factor in two cases was total dental extraction at mid-term which restricted diet to slops and caused a definite secondary dietary deficiency In none of the 23 cases, however, were there either associated polyneuritis or other gross signs of any vitamin deficiency

Serum protein was estimated in 5 cases and yielded values ranging from 5 12 to 6 3% Serum calcium in 6 cases showed figures from 9 5 to 10 5 mg per 100 c cm

The individual readings bore no apparent relation to the dietary history in these cases

Symptoms —Patients when first seen here were already in the puerperium, but symptoms had begun as early as the 3rd month, and as late as 3 weeks after delivery The average onset of symptoms was around the 7th month Severe hæmorrhage had occurred in only one case

Symptoms	Cases	Symptoms	Cases
Pallor	23	Œdema of legs	8
Jaundice	5	Paræsthesiæ	3
Breathlessness Tiredness	22	Severe, prolonged vomiting	11
Sore tongue	13	Mild diarrhœa	2

Sore tongue is usually an early, and often transient or recurrent symptom , its significance is often overlooked Œdema was related to low hæmoglobin levels rather than to lowering of serum proteins

EXAMINATION AND INVESTIGATION

Pyrexia was usual and many cases reached hospital a few days after delivery with the diagnosis of puerperal sepsis

Under treatment pyrexia lasted an average of 10 days, and was usually about 100° to 101° F It bore no constant relation to hæmoglobin level, disappearing in one case when this reached 16% and in another not until 56% was reached Two cases were apyrexial, having hæmoglobin levels of 33% and 54% on admission One case with temperature of 104° F was complicated by cystitis

Nervous system —Retinal hæmorrhage was present in 10 of the 21 cases observed , the average hæmoglobin in these cases was 20% Vibration sense and deep reflexes were normal in all cases

Alimentary system —Actual glossitis was present in 2 cases In most, the tongue was smooth and pale with atrophy of the papillæ The spleen was palpable in 3 cases, the liver enlarged in 4

Histamine test-meal —Three cases showed histamine refractory achlorhydria , 7 cases showed hypochlorhydria , 11 cases had normal hydrochloric acid in the gastric juice There was no relation between defect in diet and presence of free hydrochloric acid , in treatment, however, it will be seen that those cases which responded to 'Marmite' had free hydrochloric acid present with a history of poor diet during pregnancy

Gastroscopy was performed in 2 cases One showed an atrophic, the other a normal, gastric mucosa

Stools were examined for ova in 7 cases and were normal in all So also was ratio of split to unsplit fats

Occult-blood test was negative in all cases

Cardiovascular system —Systolic apical murmurs were present in 11 cases One case had a mitral presystolic murmur, due to associated mitral stenosis

Albuminuria was present in 8 cases, but as these were not catheter specimens it is of doubtful significance, owing to contamination with lochia

BLOOD EXAMINATION

The red-cell and hæmoglobin findings were as follows

Red cells per c mm (millions)	Cases	Hæmoglobin Hb % (Sahli)	Cases
0 –0 5	1	0–10	1
0 5–1 0	11	10–20	11
1 0–1 5	7	20–30	4
1 5–2 0	1	30–40	4
2 0–3 0	3	40–60	3

Colour-index ranged from 0 98 to 1 4 Average was 1 13 During treatment reversal of colour-index occurred in 6 cases, who all required iron to supplement liver therapy Average reticulocytes were 3% , one case had 10% reticulocytes but had been having iron from her doctor before admission The mean corpuscular volume varied from 96 7 cu microns to 157 cu microns with an average of 110 cu microns Blood films showed well marked anisocytosis with poikilocytosis, microcytosis and megalocytosis and diffuse polychromasia A Price-Jones curve was performed on one patient only, showing slight shift to right Although several of the blood films conveyed the impression of spherocytosis this was never definitely proved by correlation of MCD and MCV Red-cell fragility was estimated in 9 cases , in 3 there was insignificant increase in fragility , 6 cases showed excessive urobilinuria by Schlesinger's test Van den Bergh reactions in all cases were positive indirect , average bilirubin was 1 9 units Wassermann reaction was done in 6 cases , it was negative in all

White blood-cells ranged from 12,200 to 1300 per c mm with an average of 5200 Leucocytosis of 15,000 commonly occurs after normal delivery, so there appears to be a definite leucopenia , in most other series leucoto it in a concentration of 10–15% in true solution We conclude that since sulphanilamide is sufficiently soluble to exert a direct damaging effect on nerve it should be used with caution at operations in which peripheral nerve trunks are exposed

---

[1] Osler W *Brit med J* 1919, i, 1
[2] Stevenson E M K *Edinb med J* 1938, 81 1

SUMMARY

We have shown that the sciatic nerve of the rabbit is not capable of withstanding saturated solutions of sulphanilamide indefinitely without undergoing interruption of the nerve-fibres and Wallerian degeneration

INOPERABLE GASTRIC CANCER

TREATMENT WITH RADON SEEDS

R W RAVEN, F R C S
MAJOR RAMC, ASSISTANT SURGEON TO THE ROYAL CANCER HOSPITAL (FREE)

THE stomach is one of the commonest organs to be affected by cancer and the management of gastric cancer is an important surgical problem An improvement in the survival-rate of patients with the disease will follow advances in the early diagnosis Many patients still present themselves for treatment at a stage when radical surgical extirpation is impossible I investigated a series of 187 consecutive patients and found that in 77% the disease was so advanced that only palliative treatment was possible The only hope for the patient lies in radical surgical excision during the early phases, the operation being either partial or total gastrectomy with removal of the regional lymphatics The operative mortality will diminish as a result of advances now being made in the management of patients undergoing operations, and with increasing knowledge of the biochemical factors influencing nutrition and improvements in surgical technique Recently, for example, the operation of transthoracic resection of cancer of the cardiac end of the stomach involving the œsophagus has developed considerably

This paper discusses the management of the large group of patients in whom the disease is advanced The method of treatment described has been found to relieve symptoms and in many cases to prolong the lives of patients who are unsuitable for gastrectomy In most of the patients treated in this way the growth was in the proximal half of the stomach, where the bulky, vascular variety of tumour, growing into the cavity of the stomach but late in invading the regional lymphatics and other structures, is common Some neoplasms in this region are radiosensitive

The first patient to be treated with radium was reported by Wickham and Degrais (1914), gastrojejunostomy was performed and radium inserted in the neoplasm which regressed, the patient surviving for 18 months Janeway (1918) reported much amelioration of symptoms in 7 patients In succeeding years a number of observers reported benefit as the result of irradiation In some patients the tumour was irradiated from internal and external sources Schmidt (1928) reported that a patient survived 3 years after irradiation, Holfelder (1931) noted that one patient lived 2½ years and another one year Gosset, Monod and Regaud (1933) reported the results in 31 patients and stated that one patient survived 6½ years, another $2\frac{9}{12}$ and 3 others a year or more Pack and his colleagues (1935) reviewed the results of treatment of 60 patients and reported one patient alive after 3 years, 2 alive at 2 years, and considerable palliation of symptoms in several others Pack and McNeer (1939) studied the results in 268 patients and found that 5% benefited considerably and that symptoms were relieved in 20%

TECHNIQUE OF INTERSTITIAL IRRADIATION

In the development of the technique described I have had the help of Prof W V Mayneord in the physical side of the work After surgical exposure the size and shape of the neoplasm is carefully measured, and from graphical data the amount of radon required is estimated by the physicist in attendance at the operation, he will also indicate the most appropriate theoretical sites for the implantation of radon seeds

When the lesion is in the proximal half of the stomach a left paramedian incision is advisable An adequate exposure is essential and the site, size, shape and extensions are determined so that a correct assessment of the number of radon seeds required can be made Souttar's radon-seed introducer is pushed obliquely through an area of normal stomach wall near the lesion, and radon seeds are inserted around the growing edge of the carcinoma When the growth involves the cardiac orifice care is taken to ensure that seeds are inserted in this area Seeds are also inserted uniformly throughout the body of the tumour 1 cm apart It is necessary to re-insert the radon-seed introducer through different points in the stomach wall in order to reach the various areas of the tumour For growths approximately 12 cm by 10 cm in size 30 radon seeds of 2 millecuries each are required to secure uniform irradiation When the radon seeds have been inserted, the abdomen is closed in layers without drainage A plain X-ray picture is taken of the stomach as soon as possible to determine the position of the radon seeds

Owing to the anatomical position of the stomach and the close proximity of other vital organs, irradiation here is attended by greater dangers than is the case with the breast, mouth, and cervix uteri After irradiation of the upper abdomen, radiation sickness is common A moderate fever may develop owing to the increase of local infection in the neoplasm but it subsides quickly The blood-picture may show secondary anæmia and sometimes severe leucopenia Leakage of stomach contents through the puncture holes made by the radon-seed introducer may give rise to acute diffuse peritonitis, but this risk is minimised if the introducer is inserted at an acute angle to the stomach wall so that the sero-muscular coat is penetrated obliquely for some distance Radionecrosis with extensive sloughing of the neoplasm may develop immediately or several weeks later, and sloughing of the neoplasm may lead to hæmorrhage from the stomach or perforation into the peritoneal cavity

RESULTS

During the years 1936–41 inclusive 34 patients were treated by the method described They were suffering from inoperable cancer of the stomach, and surgical extirpation was impossible The periods of survival after treatment were as follows

Survival (months)	Under 1	1–3	4–6	7–9	10–12	13–18	19–24	25–36
No of patients	5	12	8	6	0	1	1	1

Of the whole series, 2 are still alive, one treated 3 years ago and the other 7 months ago The results must not be assessed entirely by the period of survival although in certain cases life is definitely prolonged It is reasonable to suppose that almost all these patients would have died within 3 months without treatment owing to the advanced stage of the disease Palliation of symptoms was achieved in many, thus there may be relief of pain and vomiting, improvement in general health and an increase in weight and strength, often the appetite returns When the growth has invaded the cardiac orifice causing dysphagia this symptom may either diminish or disappear In one patient gastrostomy had been performed in another hospital for complete dysphagia, but after irradiation swallowing became normal and the gastrostomy was allowed to close

SUMMARY

Treatment of inoperable cancer of the stomach by irradiation with interstitial radon-seed implantation is described

Of 34 patients with an expectation of life of 3 months, 2 are still surviving, one 3 years and one 7 months after treatment, 3 of the whole series survived for more than a year, 14 survived between 4 and 9 months, and 17 died within 3 months of treatment

The method prolongs life and ameliorates symptoms in many patients

patient, often the first sign (2) Reticulocyte response within a week, 15 cases showed over 10% reticulocytosis, this response bore no constant relationship to initially low hæmoglobin or red-cell levels (3) A sustained rise in hæmoglobin

Our cases may thus be grouped under five headings

1 Spontaneous remission on diet poor in extrinsic factor *Two cases*

2 Response to normal diet, sometimes with marmite added These patients had dietary inadequacy and free hydrochloric acid in their gastric juice *Six cases*

3 Response to refined liver extract injections *Two cases*

4 Response to crude liver extract injections *Eight cases*

5 Response to raw liver *Five cases*

Of the 17 cases in which a follow-up of over six months is possible (see table II), 8 are well with no treatment, 6 are well with no treatment except iron to combat secondary hypochromic anæmia, 3 require regular doses of campolon

SUMMARY

Of 23 cases of pernicious anæmia of pregnancy all responded to specific therapy, which could subsequently be discontinued in 14 cases

Dietary deficiency and vomiting are important ætiological factors

Free hydrochloric acid was present in the gastric juice in 18 cases, in such cases marmite added to a good mixed diet may be sufficient treatment Where there is achlorhydria or where marmite fails a response may be obtained from injections of either a refined or a crude liver extract, or failing these liver by mouth

Some degree of iron deficiency often becomes apparent during therapy

We wish to thank Surgeon Commander C C Ungley, RNVR, without whose records and suggestions this paper could not have been written, and Prof F J Nattrass and Dr J C Spence for permission to use their case records

LOCAL APPLICATION OF SULPHANILAMIDE TO PERIPHERAL NERVES

W Holmes, B A OXFD
BEIT MEMORIAL FELLOW

P B Medawar, M A OXFD
FELLOW OF MAGDALEN COLLEGE, OXFORD

(Department of Zoology and Comparative Anatomy of the University of Oxford)

Local damage to a nerve trunk has much more serious consequences than local injuries to other tissues, such as muscle, granulation tissue or fascia If the axons are interrupted the nerve degenerates throughout its peripheral extent, and the lesion can be repaired only by the slow formation of new fibres by outgrowth from the nerve above the lesion As nerve paralyses have often been reported after the systemic use of sulphonamides, it seems likely that the toxic effect of these drugs on nerve would be even more definite when they are used locally In a short series of experiments in which we have tested, under severe conditions, the toxic action of sulphanilamide locally applied to the sciatic nerve of the rabbit, we have found that large applications of the drug may cause functional interruption of the nerve and wallerian degeneration

METHOD

The sciatic nerve of the animal was exposed by an incision from the head of the femur to the knee, and finely powdered sterile sulphanilamide was packed along the nerve below the biceps muscle The nerve itself was not touched, and it remained protected by a fascial layer The animals were divided into two series, those in the first receiving a 1 g application, the others 2 g The weights of the animals ranged between 1 kg and 2 5 kg, but the relationship between the amount of drug used and the weight of the animal cannot be very significant, the most important factors are the amount of drug used and the area of tissue over which it is scattered In each experiment the nerve and surrounding muscle was covered over a length of some 4 cm

The animals were tested for sensory and motor disturbance within 24 hours of the operation Those treated with an application of 2 g were found to be insensitive to pinprick over the whole of the foot on the operated side, and they had lost the power to spread the toes, an action mediated by the peroneal nerve The animals treated with 1 g of sulphanilamide showed no such functional disturbance Specimens of nerve were removed from animals in both series for histological examination 15 days after the application The peroneal and tibial nerves at the site of application and the posterior nerve from the shank were fixed in formol saline and divided up, some of the pieces being mordanted with potassium dichromate before embedding, and others embedded directly in wax Transverse and longitudinal sections were cut, the mordanted material being stained by Weigert's method for myelin, and the rest stained with silver by a method to demonstrate axons (Holmes 1942) and counter stained with trichrome stains

RESULTS

The nerves from the animals which had received the smaller application showed no significant pathological change In those of the 2 g series, however, both the axons and myelin sheaths were degenerate at the site of application The type of degeneration differed from that seen after simple section of a nerve in that macrophages and Schwann cells were much less abundant, and removal of the myelin and axon remains was not proceeding normally. Proximal to the region of application the fibres seemed normal, and the axons were sending out regenerative sprouts into the damaged portion of the nerve Distally the posterior tibial nerve contained no intact fibres, and wallerian degeneration with Schwann cell proliferation and macrophage invasion was proceeding normally The blood-vessels of the nerve trunk at the site of application were considerably damaged, there had been rupture of their walls, and extensive hæmorrhage into the tissue and lymph spaces of the epineurium and between the nerve-fibres themselves

These experiments show that when acting for a sufficient time at saturation strength in the body fluids, sulphanilamide is capable of destroying nerve fibres and probably of interfering with the activity of Schwann cells Since Schwann cells play an important part in the reformation of new myelinated fibres in regeneration, we allowed one animal of the 2 g series to survive for 60 days after the application, to see whether regeneration was seriously delayed by the injury to the Schwann cells, but histological examination of the nerves after this length of time showed that the nerve at the site of application and the posterior tibial nerve were full of large regenerated myelinated fibres It seemed that regeneration had been as rapid and successful as possible, and that recovery would probably be excellent since the injury was a true "lesion in continuity," the axons and myelin being interrupted but the endoneurial tubes remaining intact

DISCUSSION

The effect of sulphanilamide in these experiments cannot have been due to the non-specific irritation set up by the undissolved powder in the wound site (Taylor 1942), because the reaction within the nerve trunk could only have been brought about by the sulphanilamide which diffused through the epineurial sheath in true solution. Sulphanilamide is not sufficiently soluble to exert a high osmotic pressure, it is neutral, and it is not surface-active Its toxic effect is therefore in all probability specific The fact that the nerve trunk can withstand as much as 1 g of the drug packed into the thigh space—that is, it withstands a saturated or nearly saturated solution for as long as it takes 1 g to be dissolved away—shows that the toxic effect is feeble On the other hand, the fact that it cannot withstand 2 g applied under similar conditions shows that the toxicity under unfavourable circumstances may be significant This is in accord with many clinical observations and with tissue-culture and other in-vitro tests (Bricker and Graham 1939, Fleming 1938, Osgood 1938, Jacoby, Medawar, and Willmer 1941, Bick 1942)

The test described is of course a severe one The operation site is clean and bloodless, and normal nerve is not as richly vascular as, for example, graft beds from which it is known that sulphanilamide is transported too rapidly to exert any appreciable damaging effect (Colebrook and Francis 1941) It should be pointed out that a test of this sort could hardly be expected to yield an indicative result with drugs which are much more soluble than sulphanilamide, such as *penicillin* For any chemical compound will be lethal to living cells exposed

THE LANCET

LONDON SATURDAY, SEPTEMBER 19, 1942

ANÆMIA IN PREGNANCY

BOTH here and in India anæmia in pregnancy has been coming in for attention lately. Here the increased incidence under war conditions is responsible; in India the problem is always present and on a large scale. Here microcytic is far commoner than macrocytic anæmia; in India the macrocytic types are much more prominent. The factors involved also vary—in this country insufficient iron in the diet is the main cause; in India there are many other causes, such as hookworm infestation and malaria, though dietary deficiency also plays an important part. LUCY WILLS[1] drew attention to this dietetic factor and suggested that the anæmia of pregnancy seen in India was a variety of the tropical macrocytic anæmia associated with dietary deficiency; she showed that her cases improved on treatment with 'Marmite'—a yeast product rich in vitamin-B complex—in the same way as non-pregnant patients. NAPIER and EDWARDS[2] in India investigated 467 cases of pregnancy anæmia and compared them with groups of 128 non-pregnant and 64 pregnant normal controls; patients with other causes for anæmia were excluded. Iron-deficiency was found to be very common and probably a factor in all cases, whatever the type of anæmia; their severe cases were all macrocytic, and though they agreed that nutritional defects played a part they thought that other factors must also be taken into account. They noted that if the child was born prematurely the anæmia began to improve soon after labour; many of their patients had enlarged liver and spleen, increased bilirubin in the serum and a reticulocytosis, which they consider indicate an over-active reticulo endothelium—possibly the result of chronic malaria. Finally, quite a high percentage of their patients had positive Wassermann reactions. Their theory is that pregnancy anæmia is a "conditioned toxæmia." MUDALIAR and MENON[3] of Madras reported on 103 cases of macrocytic anæmia and reached some different conclusions. In their opinion Indian and European pregnancy anæmias are similar; they got poor results from marmite, but good results from intramuscular liver therapy, whether crude or purified, and cases occurred among well-to-do classes whose diets were adequate. They conclude that deficiency of intrinsic factor (hæmopoietin) is important. The immense variety of conditions in India makes it difficult to assess these varying reports, but it is at least clear that severe anæmia requiring thorough treatment with all known hæmatinic factors is a live problem in India. None of the reported studies include examinations of bone-marrow; this omission ought to be repaired in future work and may help with classification.

By contrast, the home problem is simple. There are three main types of pregnancy anæmia here: microcytic iron-deficiency anæmia, pernicious anæmia of pregnancy, and a remaining small group of severe anæmias sometimes described as "hæmolytic" and sometimes as "refractory." The last two have had plenty of publicity because they are often severe and may be fatal, but numerically and socially the microcytic type is far more important—it is common, and although hardly ever fatal is responsible for a great deal of poor health and inefficiency before and after labour. Lately LESCHER[4] described 17 cases of severe anæmia and his records illustrate the difficulty in distinguishing between the pernicious anæmia patients, for whom treatment with parenteral liver extract is often strikingly successful, and the hæmolytic-refractory group for whom repeated blood-transfusion is the only treatment. The blood-picture gives little help; free acid is often present in the gastric juice of the pernicious-type patients, hyperbilirubinæmia may occur in either, reticulocytosis may help in the hæmolytic cases but is absent in the refractory ones. The clue may be provided by sternal puncture: if the characteristic megaloblasts are present the case is one for liver treatment, if they are absent—even though the marrow contains numerous primitive erythroblasts of other types—transfusion should be begun without delay. In other words, the criteria are the same as those laid down by ISRAELS[5] for anæmia in general and, as in non-pregnant patients, rare cases with megaloblastic marrow do occur which prove partially or completely refractory to liver treatment and need transfusion; DAVIDSON, DAVIS and INNES[6] have recorded examples. The group of 23 cases studied by MILLER and STUDDERT in Newcastle-on-Tyne, and discussed in this issue, is especially interesting because many of them had deficient diets. A state of affairs corresponding more to Indian conditions was found; some patients responded to diet alone or diet plus marmite, others who failed to respond to purified liver extracts responded satisfactorily to cruder ones. They examined the sternal marrow in 5 cases and found it megaloblastic in all.

The macrocytic anæmias of pregnancy have received disproportionate attention because of their severity and the problems involved. The microcytic anæmia is relatively simple; it is easy to diagnose—typical low colour-index anæmia—and most cases respond to proper iron treatment. It must be nearly 100% preventible, yet it is on the increase. The reason is hardly obscure. HAMILTON and WRIGHT[7] reported on 392 cases seen in London between May, 1941, and March, 1942; initial hæmoglobin values were 75–79% Haldane; iron treatment during the pregnancy increased the hæmoglobin, but when iron was withheld there was a further fall in the hæmoglobin of about 10%. In their view women of the artisan class are more anæmic than before the war, so that when they become pregnant they are at a disadvantage from the start. MACKAY, WILLS and others,[8] who examined women between September, 1941 and January 1942, remarked on the disquieting increase of anæmia among them. The report of the People's League of Health[9] showed that just *before* the war the

Reviews of Books

The Discipline of Peace

K E Barlow, MRCS London Faber and Faber Pp 214 8*s* 6*d*

By a paradox of civilisation, it is only when least can be done about it that man realises fully how dependent he is upon the fertility of the earth Many thought that the lesson of the last war had been learned for all time—that mankind would never slip back into the money-grubbing, machine-aided system under which the soil was exploited by the industrialist, and robbed of all it could yield without repayment The penalties of the system were there for all to see, the " dust-bowl " of the Middle West was a demonstration of the result of exploiting nature Rob the *soil of its natural vegetation, cart away all the new* growth of food the cleared region can produce, deplete the soil of its organic matter, lay it open to the wind and the rain, and in a few short years you have a desert Nature left alone achieves an equilibrium in which growth and decay balance, man can disturb that equilibrium without peril only if he has an understanding of the complex adjustment This is the central theme of Dr Barlow's book The gospel has been preached before, notably by Jacks and Whyte in *The Rape of the Earth*, but perhaps never with such vehemence As a physician he sees the danger to the community of blind interference in nature's system and his " discipline of peace " is the fitting of man's activities into the discipline of nature, to make an integrated whole in which man is a part of his own environment as well as that of the plants and animals on whose continued multiplication his existence depends The author has a social philosophy to preach—a philosophy based admittedly on that of Eddington but developed along the lines of biological thought, recognising the need for the integration of man and nature Without that integration Dr Barlow sees only self-destruction for the human race

Year Book of Pathology and Immunology

Editors H T Karsner, MD, S B Hooker, MD Chicago Year Book Publishers, London H K Lewis Pp 623 16*s* 6*d*

The busy pathologist with little time to read, or to abstract what he does read, will find in this yearbook a most useful cross-section of current developments in these fields The well-summarised abstracts are arranged in sections under the various systems for pathology, and under specific bacterial infections for immunology, there are shorter sections on bacteriology, allergy, antigens and antibodies, chemotherapy, and a particularly good summary on iso-immunisation and its relation to transfusion reactions and erythroblastosis fœtalis In the pathology section, which is well illustrated, emphasis is laid on ætiological factors in the genesis of disease processes good examples are Foulds's views on the histogenesis of cancer, Muir's work on the evolution of mammary cancer, Virgil Moon on morphological changes in shock, and the various factors contributing to hypertension The result is to stimulate thought on these pathological processes Among the infections, attention is mainly focused on those which are most prevalent or associated particularly with war, although more of the recent work on gas gangrene and typhus might have been noticed There are short sections on new technical methods

Preclamptic and Eclamptic Toxemia of Pregnancy

Lewis Dexter, MD, research fellow in medicine, Harvard Medical School, Soma Weiss, MD, Hersey professor of the theory and practice of physic, Harvard University Boston Little, Brown and Co Pp 415

In this exhaustive book, written from a non-obstetric point of view, the late Prof Soma Weiss and his fellow physician, Dr Dexter, had a *twofold purpose* description and interpretation of their own work, and summary and analysis of a vast bibliography which they sifted with commendable thoroughness They missed little that has been written on this subject in the last decade and for reference alone the work is valuable They approached the subject from a purely physiological point of view, and to establish what is normal they investigated a series of non-toxic pregnant women From this they passed to the pathological and experimental The whole book is a careful if mainly negative piece of work, and helps to clarify confused issues by placing the problem on a proper footing, without raising any new theories it gives material for evaluating old ones The work is well illustrated by microphotographs and diagrams It is not a book for students, but should be read by any physician *and obstetrician who is interested in the toxæmias* or who is called on to treat such cases

Race, Reason and Rubbish

Gunnar Dahlberg, MD, LLD, director of the State Institute of Human Genetics, University of Uppsala London George Allen and Unwin Pp 240 8*s* 6*d*

Professor Dahlberg's eminence as a geneticist gives authority to this lucid and dispassionately critical guide, and it is a pity that its title suggests a different tone and temper from that of the text As he points out in the preface, political discussion about the rightness or wrongness of scientific principles and conclusions is repugnant to the scientist It is however important that the public should have knowledge about human heredity as about other scientific matters that affect man's well being It is particularly necessary at a time when spurious genetic doctrines have been used to justify the savage persecution of innocent people, compulsory sterilisation on a large scale, and militant nationalism It is in the last two of his twelve chapters that Professor Dahlberg examines the racial question, especially in its application to the Jews, his sober review of the data doubtless suffices to get his book banned, if not burnt, in Germany The main chapters are devoted to the discussion of gene linkage, modes of inheritance, mutation, sex determination and linkage, mating and selection, inbreeding, cousin marriage and other special problems receive attention The style is straightforward and simple, yet dogmatic over-simplification, so tempting to the writer of popular manuals, is consistently avoided

First Aid for the Home Guard

R Morris Jones, MB Lpool, DPH, MO to a Home Guard battalion London Practical Press Pp 46 2*s*

This condensed and simplified course of first-aid training, based on larger textbooks, and modified by Dr Morris Jones's practical experience, accepts the possibility that Home Guard casualties, especially in the country, may be cut off for hours or days from the skilled attention of a doctor or of the staff at a civil defence service post It therefore proposes a comparatively high standard of training, and includes, for example, the application of the Thomas splint This splint is *not available for* Home Guards in the ordinary course of things but it might be possible to obtain one from the nearest military or civil post, and in any case there should be one with any ambulance coming to collect the wounded Presumably an ambulance will turn up sooner or later so that skill in applying this splint will not be wasted A large number of booklets have now been published by HG medical officers and they embody views which differ to a surprising degree, neither officially nor otherwise is there any agreement as to what constitutes first aid, or what methods are best for treating particular casualties Thus Dr Morris Jones makes a short reply to those who may criticise his advocacy of tannic acid in the treatment of burns, he need scarcely have troubled to do so, for his views are at least as valid as those of anybody else In spite of minor defects this is an able and useful booklet litmus, so as to minimise this danger It is still more important to maintain a large fluid intake for the same purpose Another toxic symptom which can apparently be effectively suppressed is the cyanosis which sometimes appears Admittedly this symptom is more spectacular than dangerous When it occurs, it can be removed by the oral or intravenous administration of methylene-blue ZIERZ[14] found that if 10 c cm of a 1% solution of methylene-blue is injected intravenously, the cyanosis and the subjective symptoms all disappear in 15–30 minutes, alternatively 200 mg may be given by mouth and the cyanosis will be removed in 3–4 hours Excretion of methylene-blue continues in the urine for 6 days Thionin can be used in the same way If the cyanosis is causing alarm to the patient's friends this seems to be a simple, safe and effective way of making the outlook seem less blue

Attempts have been made to influence the toxicity or the activity of sulphonamides by modifying the diet In the early days of this therapy it was thought that the toxicity—particularly the tendency to cyanosis—was increased by the presence in the diet of eggs or onions, or by giving the patient aspirin or phenacetin More recent opinion, such as that of FAIRLEY[15] denies the need for these restrictions on diet or treatment In particular, since eggs are such a valuable food in illness, it is important to recognise that they can safely be used during sulphonamide therapy A different aspect of the problem is presented in several recent American papers ROSENTHAL[16] has lately demonstrated that the therapeutic activity of sulphanilamide, tested in mice infected with streptococci, is less if the mice are fed on a high protein diet than if they are given a carbohydrate one, this seemed to be due to a lowering of the blood concentration of the compound on the high protein diet Similarly SMITH, LILLIE and STOHLMAN[17] have shown that a high protein diet diminishes the susceptibility of rats to the toxic effects of sulphanilamide Therefore a high protein diet reduces both the activity and the toxicity of the compound STOHLMAN and SMITH[18] find that in fasting rabbits given sulphanilamide by mouth excretion in the urine is delayed and consequently the blood concentration is raised, compared with normally fed rabbits The differences observed are not large enough to be of clinical importance, but they indicate the need for standardising the dietary conditions of laboratory animals used for testing these compounds

THE WOMEN'S SERVICES

THE admirable report which has just been issued by Miss VIOLET MARKHAM's committee (see p 343) will bring comfort to many parents and ease the anxieties occasioned by unfriendly rumours, most of which have little or no foundation in fact The report is critical but sympathetic It describes a great task carried out with imagination and foresight Mistakes and blunders have been made, this was inevitable in the hasty building up of new services under war conditions They may well be forgotten in looking at a picture of ever-increasing usefulness and efficiency The call to the Forces has brought together thousands of young women from all sorts of homes, many of whom would never otherwise have had the opportunity of familiar association with girls differently brought up This mingling of classes is a great social experiment, it gives a chance to create a better understanding and a broader outlook among women Different ideas of personal hygiene and different table manners are obvious difficulties in community life The discipline of give and take, of learning to do as you would be done by, is new to many but none the less wholesome The report wisely stresses the importance of looking to the future and making the fullest use of the means offered by Service life of improving not only health but character, and of training not only for immediate duties but for work under the difficult circumstances of a post-war world Perhaps the most disappointing finding the committee make is the lack of interest shown in education and in reading, which so far seem to have failed to arouse any enthusiasm except among the few Facilities are not yet fully organised It is to be hoped that it will be possible to expand them on the lines suggested so that to many of these women education may indeed become " a great adventure " and the gateway to those wider opportunities which we want them to enjoy in days to come, and for others will at least abolish much of the boredom and monotony which is so fertile a source of trouble

The well-being of the women under her command is described as the primary duty of the officer It is satisfactory to note that health is in general extremely good and that the life leads to an improvement in physique, poise and self-confidence as well as in mental stability No softness is looked for women must be prepared to rough it if the exigencies of the service demand this, but a minimum of " Spartan decency " must be granted if health and morale are to be preserved, this includes reasonably comfortable accommodation, cleanliness, warmth good food and medical attention The officer and the doctor are both concerned with various matters of personal and general hygiene, and can be mutually helpful The medical care of large groups of healthy women is a task for which women doctors are well suited and the report calls for an increase in the number of those already employed They are notably required in the reception stations for WRNS and in each Naval Command where none have yet been appointed Hitherto medical women have striven in vain to induce the Admiralty to make such appointments More women gynæcologists are needed, especially in stations, so that the women can have ready access to them It is interesting to note that the more active the occupation the less menstrual disturbance there is likely to be, perhaps this observation may finally explode the legend of feminine incapacity for strenuous work because of periodic disability due to menstruation The experimental work in the ATS and the WAAF in mass radiography of the chest is of special interest in view of the susceptibility of young women to tuberculous infection and the possibility of an increased mortality under war conditions The doctor's duties may not offer extensive opportunity for clinical treatment, but they do include all that is necessary for an invaluable experiment in social medicine, and for implanting that desire for health iron intake of 98% of the London women investigated was insufficient With the restriction of iron-containing foods, especially meat, that the war has forced on us the situation has certainly worsened and increased incidence of anæmia is the result The Ministry of Food has shown commendable concern for potential and nursing mothers, but to provide extra milk and not enough iron is like filling up a car with petrol but omitting to charge the batteries Such a policy fails to take into consideration the increased need for iron in pregnancy, which **Balfour**, **Hahn** and others[10] have recently shown varies from 2 to 10 times normal Only a super-optimist could think that the feeding of our women is likely to be any better during the coming winter To close this gap in our nutritional armour and to prevent the ill health that even mild degrees of anæmia bring with them will require the cooperation of all the bodies responsible for the health and nutrition of the people If all pregnant women had antenatal medical supervision prevention would be easy, but they don't, so other methods must be used The Ministry of Food could consider an increased meat as well as milk ration—the suggestion[8] of iron-fortified milk would be difficult to carry out The Ministry of Health could see that all antenatal clinics are alive to this problem and that adequate supplies of active iron preparations are available for their use The doctor who has pregnant women in his care should regard every one of them as a potential anæmia case and treat accordingly with iron—no liver treatment is called for unless a firm diagnosis of pernicious anæmia of pregnancy is made If these measures are taken in time, before the winter is on us, pregnancy anæmia, instead of increasing, ought to be reduced to practically nil and all the potentially severe cases could be caught early This is a job worth doing thoroughly

MODIFYING THE TOXICITY OF SULPHONAMIDES

Many attempts have been made to discover some way of reducing the toxicity of sulphonamides which often handicaps their therapeutic use When poisonous substances are introduced into the circulation the body usually tries to render them innocuous by conjugating them with other compounds to form less toxic combinations, this conjugation may be preceded by either oxidation or reduction The compounds used to form these combinations are aminoacetic acid, choline, cystine, glucuronic acid, glutamine, sulphates, acetates and ornithine In the case of sulphonamides the major part of the detoxifying process consists of conjugation with acetates to form the acetyl derivative which is then excreted in the urine **James**[11] found that in mice the proportion of sulphanilamide which thus became acetylated could be increased by giving sodium acetate with the drug, the acute toxicity of the drug was thus somewhat reduced while its curative action against streptococci seemed to be unchanged There is one paradoxical aspect of this work, however—that acetylsulphanilamide is more toxic for mice than sulphanilamide itself

Lately a group of American workers[12] have found that the mortality of mice receiving toxic doses sulphanilamide, sodium sulphapyridine or sodium sulphathiazole can be reduced by 40% if the mice simultaneously receive calcium glucuronate, ascorbic acid, or a mixture of these with cysteine, glutamic acid and aminoacetic acid A large range of other compounds were relatively or completely inactive Sodium acetate diminished the mortality by 20%, The therapeutic activity of the sulphonamides seemed to be undiminished, but this is impossible to measure accurately The detoxifying action of the various compounds was not due to delay in the absorption of sulphanilamide from the alimentary canal, since in dogs it was found that they actually accelerated absorption At first sight this work offers a promising method of diminishing the toxicity of sulphonamides in clinical practice, but second considerations indicate the need for caution In the first place the theoretical conceptions on which this procedure is based contain an important inconsistency While it is probable that the toxicity of a drug may be reduced by hastening its conjugation with detoxifying compounds, it is equally to be expected that the therapeutic activity would be diminished to the same extent Failure to observe this diminution of therapeutic activity may easily be due to the difficulty of measuring it with any degree of accuracy **Martin** and his colleagues do not present the actual experimental data from which their conclusions are drawn, so that it is impossible to assess the true weight of their evidence, and the diminution of toxicity which they observe is relatively slight A more important obstacle to the clinical application of this work is the difference in the bases for the acute toxicity of sulphonamides in mice and for the chronic toxicity which they may cause in man Thus the acute toxicity of mice seems to be associated with acidosis and with effects on the central nervous system In man, on the other hand, the most important toxic effects are agranulocytosis, renal obstruction, skin rashes and vomiting, while those due to the nervous system are seldom serious It will therefore be advisable to wait for more conclusive evidence to be produced before expecting to reduce the clinical toxicity of sulphonamides by these methods

There is a possibility of diminishing or avoiding some of the toxic complications by other less ambitious procedures, directed against a single specific complication rather than against the general toxicity Thus one of the most serious sequelæ to sulphonamide therapy is anuria due to blockage of the renal tubules or ureters by the less soluble acetyl derivative Although this is practically unknown with sulphanilamide, it is not uncommon after sulphapyridine, sulphathiazole and sulphadiazine Many workers have shown that both sulphonamides and their acetyl derivatives are more soluble in alkaline than in acid urine, and **Climenko**, **Barlow** and **Wright**[13] have given a striking demonstration of how the simultaneous administration of sodium bicarbonate protects the kidneys of monkeys from the injury which would otherwise follow heavy dosage with sulphathiazole When sulphapyridine, sulphathiazole or sulphadiazine is given clinically there is good reason for giving sufficient bicarbonate to keep the urine alkaline to ponent of blast probably plays a primary part in the causation of these blast injuries It is difficult to reconcile this view with that derived from observations made with actual explosions Zuckerman and his collaborators[1] have reported experiments which show that blast injures the body not by way of the mouth and nose but primarily as a result of the impact of the pressure component of the wave on the body wall When animals were placed so close to small explosions that the near side shielded the opposite side from the impact of the positive component, lesions were always concentrated on the side nearest to the explosion, although both sides were subjected equally to the suction phase In other experiments blast lesions were observed when animals were exposed to the pressure component of blast alone Moreover, as reported by Rex Williams in his Hunterian lecture, typical blast lesions occur as a result of under-water explosions, in which the suction component is of far shorter duration than that of blast in air—of such short duration in fact that for practical purposes it is usually regarded as non-existent It seems probable, therefore, that the conditions of Latner's experiments were not sufficiently related to those of a true explosion to justify the conclusion he has drawn He gives no measurements of the duration of the decompression to which his animals were subjected, and it is difficult to see how the duration could have been as short as that of the suction component of blast While they do not appear to relate strictly to the question of blast, however, his experiments obviously have a bearing on the important aviation physiology problem of explosive decompression

EHRLICH AND ZIEHL NEELSEN

FEW tests in clinical pathology have withstood the ravages of time so long as the fuchsin acid-fast method of staining the tubercle bacillus We are accustomed nowadays to refer to it as the Ziehl-Neelsen technique, but, as Prof W Bulloch pointed out, the stain as we know it today is primarily the invention of Ehrlich, the modifications of Ziehl and Neelsen being trivial Many attempts have been made to improve its technique but the fundamental principle and practice are still unchanged The two directions in which modifications have usually been suggested have been the substitution of a less potent decolorising fluid for the sulphuric acid, or the use of a less intense counterstain which does not obscure the fuchsin stained bacilli Sulphuric acid substitutes came into vogue again during the last war on the grounds of economy The counterstains have a still longer history, Carl Spengler many years ago introduced picric acid and later A D Gardner showed how easy it was to miss the red-stained bacilli on the deep blue background of methylene blue in the strength in which it is generally used Colour contrast is of course essential and as some degree of red-green colour blindness is by no means infrequent in the male it might be prudent to avoid green as a counterstain Yellow and brown have the advantage over blue that they do not overstain but the disadvantage that the colour contrast is less vivid J E Pottenger[2] has returned to the quest with a host of suggestions and modifications, though even he leaves the foundations of the stain unassailed He begins by increasing the amount of basic fuchsin in the stain from the usual 1% to 1·2% or 1 5% With a series of 70 sputa he found he could raise the efficiency by this means up to 46%, controlling the intensity of the staining meanwhile by placing a small film of a known positive on the same slide as the specimen under investigation He found too that by treating carefully standardised films with different counterstains and with no counterstain at all he could grade the efficiency of a light or dark background for the bacilli in the following order of merit picric acid, no counterstain, methylene-blue 1/150%, malachite green 0 02%, Bismarck brown 0 05%, malachite green ½ saturated, Bismarck brown 1%, methylene-blue 0 1%, and methylene-blue 1% The last, therefore, which is perhaps the commonest counterstain in use, is the worst He brought out other subsidiary points in the classical acid-fast staining technique for the tubercle bacillus, and finally issued a questionnaire to 23 institutions on the subject, setting forth their answers in a separate paper From these the cardinal fact stands out that, though most workers adhere to the standard carbol-fuchsin stain, useful modifications can be applied, and will increase the proportion of positive tests without adding to the labour of technicians in the daily routine of the laboratory—a point which is not always sufficiently appreciated by research workers who do not deal with thousands of tests per annum

RAT-BITE FEVER

THE general belief has been and probably still is that *Spirillum minus* is the cause of rat-bite fever, but cases also occur from which *Streptobacillus moniliformis* can be isolated Japanese workers have always stressed the spirillar ætiology since the organism was first described as a spirochæte by Futaki[1] in 1916, its name being changed to spirillum in 1924 However, Schottmüller[2] in 1914 described two strains of streptothrix isolated from patients bitten by a rat and a squirrel, and several workers have since isolated similar organisms Most of these were probably what is known as *Sb moniliformis* and is now more readily isolated on the special medium which has been devised for its growth In 1933 Strangeways[3] showed that *Sb moniliformis* was apparently a normal inhabitant of the nasopharynx in 50% of laboratory rats and she also found it in four wild rats This is a striking contrast to the unsuccessful attempts to demonstrate the spirillum in the mouths of rats Though recent reliable data are not available from Japan, in England and the United States this infection seems to be much commoner in rats than *S minus* In reviewing all the cases that have been reported in the USA Brown and Nunemaker[4] note that of 9 cases in 1939 and 1940 an alleged ætiological agent was isolated in 5, *S minus* once and *Sb moniliformis* four times Recently Larson[5] has reported 3 cases of rat bite fever from one of which *S minus* was obtained by animal inoculation, *Sb moniliformis* was obtained from a second and was also considered the ætiological agent by agglutination only in a third Brown and Nunemaker have described 3 cases from which they have isolated the streptobacillus and 5 in which the presumptive diagnosis was made on agglutination tests Like all previous investigators they have failed to find both the spirillum and the streptobacillus in the same case Though the spirillum has been the only agent isolated by the Japanese from their cases of sodoku they have reported clinically typical spirillum-negative cases which may have been caused by the streptobacillus The last cases described in this country were 2 in 1936,[6] both following cat-bite, and from only one was the spirillum isolated Brown and Nunemaker point out an obvious overlapping of the main clinical features of the two types of infection (leucocytosis, rash, relapsing fever positive serological test for syphilis, response to arsenical therapy and arthritis) The clinical picture produced by the natural infection is fairly typical The initial wound usually heals without signs of local inflammation One to three weeks later an area of purplish induration appears at the site of the bite, usually without suppuration Lymphangitis and

about which we hear so much Not all doctors can teach, but those who can should be able to give great practical assistance both to officers and to the rank and file in handling such difficult matters as venereal disease, sex behaviour, and emotional problems Arrangements for dealing with maternity patients are not adequate As far as they go they are humane and efficient, but there is not enough provision for the confinement itself, for the weeks before and after, or for the residential care of small children There are substantial numbers of married women with the Forces, and it is for them as well as for the single girls, comparatively few in number, that better facilities are needed Many have no homes of their own or relatives who can receive them This is, in the words of the report, a national and not a service problem The country has required the work of many young married women who would normally be living at home It is due to them and to their husbands that every care should be taken of them during and after pregnancy, and that suitable and acceptable arrangements should be made for the confinement and for the care of their children if they wish to return to duty

The nation owes an unquestionable debt to its girls and women They are carrying a heavy burden, only justified by a desperate emergency We have taken them away from their homes, parted them from friends and children, completely altered their social habits But we have also given many of them a wholly fresh outlook on life, new and exciting jobs, the chance to show that they can make good in all sorts of unfamiliar occupations They have adapted themselves readily to new tasks hitherto deemed unsuitable for women and often involving physical danger They have shown great aptitude for delicate manipulation and an unexpected enjoyment of heavy work If we safeguard their mental and physical health, develop their character by the kind of education which will stimulate their intelligence and give them the ambition to use and not waste their often excellent brains, much will have been done not only to repay the debt but to ensure the active partnership of women in shaping the new world

NUPERCAINE AND PROCAINE

To avoid future confusion Messrs Ciba have decided to discard the trade name ‘ Percaine ’ and substitute for it the name ‘ Nupercaine ’ by which this local anæsthetic is known in America The name of the ointment containing the drug will similarly be changed from ‘ Percainal ’ to ‘ Nupercainal ’ The change should draw attention to the fact that this is a proprietary drug commonly used in $\frac{1}{2}$ to 1 per thousand dilution and in a dosage of up to 100 c cm for infiltration anæsthesia, whereas procaine is used for the same purpose in a dilution of $\frac{1}{2}$ to 1 per cent and in a dosage of up to 200 c cm Even now there may be muddles if every surgeon refers to procaine by the trade name of his favourite brand Lately Raymond Green (*Lancet*, Aug 22, p 231) urged makers of endocrine products to market them simply as œstrone (Smith), progesterone (Jones) and so on It would be a blessing to both prescribers and dispensers of local anæsthetics if makers of procaine would relegate their brand names to second place and market their products as procaine (Smith) or procaine (Jones)

TRAINING FOR CHILDBIRTH —The sentence dealing with instrumental interference in a leader last week (p 312) should read Among the primiparæ it varied from 23% to 50%

VILLAGE EPIDEMIOLOGY

It is not surprising that many Milroy lecturers of recent years have dealt with the effects on health of industry and of the factors producing disease and incapacity for work among town dwellers The lecturer for 1942 [1] has swung back for his material to the countryside, taking as his subject epidemic disease in English village life in peace and war Lecturer and subject were well chosen, for Pickles of Aysgarth not only know English village life, as many other doctors do, but ha brought to his everyday work during 30 years of country practice a flair for accurate observation and sufficient tenacity of purpose to record what he found, so that over the years his experience has not become woolly or been lost, as experience of the kind is apt to be, but is still available as a library of information on epidemiology and clinical medicine and on the whole province of human biology This is his plea “ I should like to make a strong appeal to country doctors to use their opportunities and to keep diligent records preferably in chart form and I firmly believe that, given even a small number of chart-keepers pooling facts, much would be learnt about the behaviour of epidemics and much vagueness in the knowledge of method of spread, of the subclinical case and the rôle of carriers would disappear ’ These lectures breathe the spirit of the countryside, and it is easy to visualise with the author the cheerful, high spirited bus loads of country folk exchanging jokes and germs, as they make their pilgrimages from the Wensleydale villages to market or to cinema in country towns One can imagine that Pickles knows them all—their families, their stock, their merits and their human failings , Betty, the rather sick little bridesmaid who was taking mumps the remarkable family with the susceptibility to acute rheumatism and mitral stenosis, the pathetic little fellow of 40 (since died of a tuberculous kidney) the origin of whose attack of epidemic jaundice could not be placed until his faithless sister gave away his nightly pilgrimage to help the infected Margaret with her household duties From such material Pickles has crystallised his views “ From a study of the literature and my own experience, it seems clear to me that there is only one form of non spirochætal jaundice in this country and that it is remarkably true to type The disease appears to be transferred from patient to patient by direct contact, probably by droplet infection ” There are stories of outbreaks of influenza and scarlet fever of measles, of german measles, of chickenpox and shingles, of epidemic myalgia and of diphtheria, and particularly of the success attending early efforts to protect the children of the Dales against diphtheria , for he believes that it should be the duty and pleasure of all family doctors to be satisfied that the children they see growing up around them are immune to diphtheria There is a tail-piece about the effects of war on village life, about the incoming of evacuees with its minor trials but comparative freedom from serious epidemic disease and the recorded belief that in the end the mingling of incomers with the native population has proved to be for the good of both

CAUSATION OF BLAST INJURIES

In the experiments reported in our last issue (p 303) by A L Latner, mice were suddenly decompressed by opening a tap between a large exhausted chamber and a small one in which the animals were breathing at normal atmospheric pressure As a result of this explosive decompression a pathological syndrome developed which was in general similar to that caused by blast, but in which abdominal changes appear to have been more extensive Latner’s conclusion is that the suction com recently treated 50 cases of functional uterine bleeding with antimenorrhagic factor in the form of 'Glanules' (Armour), the dosage employed varying with the severity of the hæmorrhage Patients who were actually bleeding when examined were usually given two glanules three times a day and this dosage was persisted in until the hæmorrhage stopped Patients who menstruated regularly but lost excessively at the periods received one or two glanules three times daily during the week preceding the menstrual flow Treatment was always persisted in for at least three months The results are encouraging, 46 out of the 50 cases were followed through, in 28 a complete cure was obtained in 4 the condition was so much improved that further treatment was deemed unnecessary, and 14 cases only were classed as failures Unfortunately the endometrium was examined microscopically in only 13 cases of this series It would be interesting to investigate the coagulability of the blood in patients before and during a course of treatment with antimenorrhagic factor

Special Articles

THE WOMEN'S SERVICES

THE nation is responsible for the women it has called into the Services and they are of vital importance because, as the committee appointed to inquire into their welfare bluntly reminds us, the auxiliaries of today are the wives and mothers of tomorrow The wider implications of the committee's sensible and sensitive report[1] is discussed on another page, but the section on health and hygiene is of outstanding interest to the doctor The committee urges that the three Services should keep uniform health records, for we are being given a unique opportunity to collect data about the health of normal women On the whole the committee found the health of the women good, even the first month's training brings improvement in physique, poise and self-confidence Entry to the services is through the doorway of medical examination by medical boards set up by the Ministry of Labour Where possible one member is a woman doctor and the boards are in touch with local authorities The women are put into four grades of which the WRNS accept only grade I and the other services grades I and II The error in selection is said to be under 1 per 1000 in the ATS and WAAF At the reception centres the women are again examined for infectious diseases and head infestation and in the ATS and WAAF, by mass radiography The ATS carry out selective intelligence tests before the medical board examination and those in the lowest grade—about 5%—are rejected forthwith The committee thinks this system should be adopted by the other two services At present a psychiatrist examines WAAF recruits who score less than 15 on the GVK test at the reception centre and those who are diagnosed as subnormal are discharged Recruits to the WRNS bring personal references, but are given no intelligence tests

As in industry the sickness rates for women in the Services are about twice as high as those for men The special ailments of women account for some of this increase, but it is noteworthy that the greatest incidence of sickness, including menstrual disorders, occurs among the women who are doing the less active duties Medical attendance hospital and dental treatment have been planned with care, but in practice individual delays are inevitable in a system where the sick have to report at a fixed time and place MOs visit billets when a woman is too ill to attend sick parade The amount of dental treatment needed is a revelation The committee was uneasy about the treatment of minor ailments Women in distant billets are said sometimes not to receive prompt attention and mistakes have been alleged in diagnosis and treatment The committee has no reason to believe that inattentiveness or lack of skill are common, but they have received a number of these complaints and urge commanding officers to see that rules are strictly enforced The committee is also concerned over the catering arrangements for girls who are allowed to stay in their own quarters with a temporary indisposition They are served with the ordinary daily ration, although sausage and mash and rolypoly pudding for instance are unsuitable for anyone with a sick headache Girls are also said to have to get up to fetch their food Regular medical inspection parades have reduced the incidence of nits to less than 2% as compared with 25% among control civilian groups, but it is still high at some reception centres

The numbers and distribution of doctors and beds seem adequate, but there should be more women gynæcologists especially on stations The Army and Navy medical services have women on their directorates and a similar appointment is to be made for the RAF The committee recommends that the WRNS should post women MOs to large reception and training centres and that the other services should increase their establishments at these centres The RAF have lately instituted at smaller sick quarters a combined post of a nurse and health welfare sister who acts with acceptance as health confidante to the women The RAF medical branch is now replacing about half of its male nursing orderlies with women, and the committee thinks these women should, if they wish, be given an opportunity to train for the nursing profession Wise and clear instructions on the care of the body, cleanliness and diet are given to recruits and there is a special lecture on personal hygiene, which in the WAAF also deals with pregnancy and venereal disease The committee heard this lecture which was given by a woman doctor and though they approved of its matter, they were not satisfied that it should be given to a large audience of recruits of all ages They suggest that a lecture agreed between the medical and educational branches on the wider implications of sex behaviour should be given to auxiliaries and that training courses for officers should include discussions initiated by outside lecturers on personal relations, the psychology of sex and the sociological implications of the family

Personnel suffering from neurological and psychiatric disorders are treated in appropriate Service hospitals and consultants are available Unstable women are referred to a Service psychiatrist who can recommend their discharge where adaptation to service life is proving too difficult The incidence of psychosis in the ATS and WAAF amounts to 0 64 per 1000 (in civilians 0 85 per 1000) and these figures relate to a period before intelligence tests were in use

Illegitimate pregnancy is almost certainly less common in the Services than out of them, but many married women become pregnant Among single ATS personnel the pregnancy rate is 15 4 per 1000 a year in the same age-groups among civilians the illegitimate birth-rate is 21 8 The care of these expectant mothers is humane and efficient There is a discharge depot for those requiring emergency accommodation for a limited period where they are put in touch with voluntary societies who help them to make arrangements for their confinement and future Facilities have so far been adequate but the situation is becoming more difficult The committee dubs this a national not a Service problem and urges the Ministry of Health to make grants to local authorities and voluntary associations for the care of pregnant women and to provide more maternity and convalescent homes and residential nurseries for the children of mothers who wish to return to the Forces

Figures show that the incidence of venereal disease among Service women is half that among the men and the committee was impressed by its low incidence Arrangements for diagnosis and treatment are adequate, but more women MOs might be employed in the gynæcological wards of the hospitals

Hours of work are on the whole not excessive, but the committee deprecates the Service policy of arranging watches with irregular hours of duty in order to get longer free periods, which they suspect must be injurious to health For continuous shift work the committee considers periods of a fortnight between change-overs would allow adaptation to the rhythm of waking and sleeping They also recommend a maximum 8-hour day and 48-hour week and the introduction of adequate rest pauses regional lymphadenitis develop and the patient has fever After several days there is a remission of the fever and inflammation of the wound lasting 3–6 days followed by a second bout of fever and increased inflammation This process may be repeated several times and is usually accompanied by a rash Severe muscle pains and occasional joint pains are usually a feature of some stage of the disease Some cases subside spontaneously but others go on for months Response to treatment with one of the antisyphilitic arsenicals is dramatic and complete Proof of the clinical diagnosis may be obtained by inoculating the patient's blood, lymph gland from the region involved or a piece of the excised wound into guineapigs and mice shown not to be harbouring any spiral micro organisms, and by culture on the special solid and liquid media[4 7] essential for the growth of the streptobacillus Recent experimental work on the treatment with gold salts of streptobacillary and the related pleuropneumonia group infection in mice and rats suggests that this may be the most effective treatment for this type of case The streptobacillus may also *cause an epidemic disease* unassociated with rat-bite, the so called Haverhill fever[8] In one such epidemic involving 86 people the infection was traced to unpasteurised milk or ice cream from one dairy After an incubation period of one to three days there was an abrupt onset with chill, headache, vomiting, a blotchy maculopapular rash and arthritis The *arthritis*, which was *the* most persistent symptom, is also seen in the cases produced by rat bite and was present in a quarter of the patients inoculated with the *S minus* by Hershfield[9] as a treatment for paresis Savoor and Lewthwaite[10] have demonstrated a well-marked rise in *Proteus XK* agglutinins in rabbits inoculated with three human and two murine strains of *S minus* isolated in guineapigs These strains, which were proved to be uncontaminated with *Proteus OXK* bacilli, gave a higher titre in the rabbit than did *Rickettsia tsutsugamushi* However, in 3 men and 4 monkeys infected experimentally with *S minus* the Weil Felix reaction remained negative Their evidence suggested that there is an OXK component in *S minus* unconnected with rickettsia in general It is significant that Felix[11] found agglutinins or relatively high titres for one or the other X type in the sera of normal tame rats, probably due to infection with *S minus* It would be interesting to know if *Sb moniliformis* has the same effect

[1] Report of the Committee on Amenities and Welfare Conditions in the Three Women's Services Cond 6384 H M Stationery Office 1s The committee which was appointed on Feb 24 1942 consisted of Miss Violet Markham (chairman) Miss Thelma Cazalet, MP Mrs Walter Elliot Major J Milner, MP Air Vice Marshal Sir David Munro MB, Mrs J L Stocks Dr Edith Summerskill MP, and Major General Sir Frederick Sykes, MP The secretary was Mrs A C M Gulland

THE GALL-BLADDER AND THE HEART

How many surgeons have operated on patients with coronary disease in the belief that they had lesions of their gall-bladders, and how many cardiologists have diagnosed coronary disease when the gall-bladder was primarily at fault? The confusion was considerable at one time and feeling ran high Today, though the association is generally recognised it is still often difficult to differentiate between the two, or, if both are present, to decide whether surgery is indicated for the diseased gall bladder That lesions in the gall-bladder or the main biliary ducts affect the coronary circulation reflexly has been confirmed by Gilbert, Fenn and LeRoy,[12] who had already demonstrated the effect of gastric distension on the coronary circulation Gilbert and Sheridan have also shown in the decerebrate dog that there is a reduction in the coronary flow on distension of the gall bladder or distension or irritation of its ducts—a reflex which does not appear after the *administration of atropine* Ravdin, Royster and Sanders[13] report 4 cases of gall bladder disease with cardiac complications relieved by surgery In 2 of these patients they reproduced an almost exact simulation of the original anginal attacks by distension of the common bile duct postoperatively In one patient they found at operation a thick, kinked common duct, plastered with adhesions and containing some "sand" They freed the duct of adhesions irrigated freely and left a T-tube in situ The patient obtained immediate relief from her attacks of precordial pain On several occasions after operation, experimental raising of the pressure in the common duct to 450–500 mm of water produced an anginoid attack Similar results were obtained in the other patient and here relief was obtained by the administration of amyl nitrite when the common duct pressure had been raised to 400 mm of water The experimental evidence is impressive, but one of the difficulties in assessing its clinical significance is the refusal of many observers to differentiate between substernal and precordial pain Only substernal *pain can be taken* as definitely diagnostic of angina pectoris, many other conditions, both cardiac and functional, must be excluded before a definite diagnosis of angina pectoris is justified when the pain is precordial This is well illustrated by Ravdin and his colleagues, who report "precordial pain (radiating) through to the back and down the ulnar aspect of the *left arm to the finger tips*" *and* "*recurrent* attacks of pain in the left side of the chest under the left breast" These may well have been attacks of angina pectoris, but it would have been clearer to describe the pain as substernal if that actually was the site of it In differentiating cardiac and biliary pain it is essential to take a careful history, this, with a full examination, will usually settle the issue Whether surgery is called for can only be decided on the merits of each case A major abdominal operation should be avoided unless it is decided that the primary cardiac damage is of less moment than the lesion of the gall bladder or main biliary ducts, or that recovery from coronary or myocardial damage is being hindered by the biliary lesion Atropine in these cases will give relief and reduce reflex stimulation of the coronary vessels to a minimum The surgeon should remember that all existing evidence shows that lesions of the biliary tract can only produce cardiac symptoms when the coronary vessels are diseased

THE ANTIMENORRHAGIC FACTOR

A SIMPLE clinical observation provided the stimulus for investigations into the antimenorrhagic factor It was noticed that when anæmic women who complained of uterine hæmorrhage were treated with liver extract not only did their anæmia improve but the hæmorrhage which had produced the anæmia often stopped also Only the cruder forms of liver extract possessed this property of stopping uterine bleeding, when the more refined types were used the *hæmorrhage was* uninfluenced Wiles and Maurer[14] came to the conclusion that since the actual purification of liver extract was not likely to destroy any of its constituents the antihæmorrhagic factor must have been removed in the process Inactive proteins and lipoids constitute most of the discarded material and it seemed that the antihæmorrhagic factor *must* be *contained in* these substances Wiles and Maurer therefore worked on beef and hog liver fat They saponified this in alcoholic potash for an hour and obtained an orange non saponifiable residue which was found to be remarkably *effective in checking* functional uterine hæmorrhage Better results were obtained in young women than in those near the menopause, and in young women the substance was said to have a cumulative effect Sutherland[15] has

rotas This amendment was lost, but a more moderate amendment, moved by Dr C W Somerville (Lothians) and sponsored by seven other divisions, was carried This proposed that in any reorganisation of general practice as full a measure as possible of free choice of doctor and patient should be preserved

GROUP PRACTICE

The chair moved on behalf of a large number of divisions that group practice should be a feature of any future medical service Group practice was defined here as referring to general practitioner practice only Dr Geoffrey Priestman (Bradford) moved an amendment that it should be "a feature but not an essential feature" of any future medical practice Dr Craig believed that every body of medical men should have a form of group practice, but he was against letting any Government department choose the set of men he should work with Group practice like marriage must be founded on affection, not on force Dr William Yeoman also feared the danger of incompatibility, but Dr Philip Inwald was more robust about it all He remembered that when he was a student he had worked happily with his colleagues as part of a team, and he thought it time for qualified men to begin working together in well-equipped centres Dr S Wand said that if group practice was good for the patient then we must have it Dr C F T Scott pointed out that in partnerships we already had a form of group practice Moreover the team of partners had access to consultant and X-ray services in the hospitals Would health centres—which somehow suggested to him pill-boxes (presumably in the military rather than the pharmaceutical sense)—have the equipment now available in a hospital? It would be extravagant to equip them with X-ray plant, for example, unless expert radiography and interpretation could also be provided Dr W W Fox said bluntly that if doctors working together could do better than doctors working alone, then the profession must support the principle of group practice The amendment was lost, and the original motion in favour of group practice was carried, modified by the provisions that it should not involve the introduction of supervisory control in clinical matters and that the groups should not be formed arbitrarily by any outside authority, they should be arranged by the doctors themselves Speaking on the last point Sir Kaye Le Fleming said that to his mind the whole report drew too much attention to the measures to be introduced by somebody else somewhen and somehow We could as a profession bring about reforms of our own before they were forced on us from outside

MEDICAL CARE FOR ALL?

Speaking to a motion that provision of whatever character should be made by the Government for the whole community, Mr H J McCurrich (Brighton) remarked that if benefit was extended to the dependants of all insured patients only 10% of the population would be excluded To administer such a scheme there would have to be 12 clerks for every doctor, and the capitation fee would vanish in expenses Dr A T Rogers was also in favour of the motion, if the meeting disagreed, he said, they would be retaining the right to exploit those outside the scheme and to give less than the best service to the remaining 90% Treating rich hypochondriacs took up time which the doctor could spend to better advantage on his panel patients Dr Inwald pointed out that in Russia and Scandinavia the Government was responsible for the service to the whole community, and the health of the people had not suffered Because a complete scheme was provided, he said, there was no reason to forbid people who wished from seeking private medical care Dr H S Pasmore feared the Government might interpret the motion as a request for a state medical service At this point the meeting caught the full flavour of Dr Rogers's red herring and several speakers explained warmly how much better they treated their panel than their private patients Sir Kaye Le Fleming changed the scent by remarking that no Government was going to introduce a revolutionary scheme for the whole nation which would mean scrapping all existing machinery Dr Fox asked how it could be a revolution if the machinery for 90% of the community already existed? He added the unusual ætiological flight that Sir Kaye's red herring had been drawn across the path in order to give the meeting a myopic eye Dr D F Whitaker said that comparable arguments had been used against National Health Insurance thirty years ago, yet no responsible body had ever asked for its repeal We should try to give equality of opportunity in medical service Those in favour of the motion, he noted, were the younger members who were going to have to work the scheme Dr Wand pointed out that if 90% were covered, treatment would still be available for all, and Dr Arthur ventured to remind the meeting that there was no scheme yet to cover even 90% If the Government brought in the dependants of insured persons, he said, it would be a long step in evolution, and to give free treatment to those who could afford to pay for it was not giving equality of opportunity Mr McCurrich could not see that to extend medical care to the whole community was any more of a revolution than to extend education to all children By a close vote—94 to 92—the motion was carried

Mr M S Fraser (Cumberland) proposed an amendment that the patient should have the right to contract out of any scheme and the doctor the right to charge fees to patients not on his list Dr Craig pointed out the analogy with education, in which people contracted out and sent their boys to Rugby, Harrow or Borstal If anyone preferred to be exploited by a private doctor he added in a pardonable confusion of nursery rhyme, then "goosey, goosey gander, come and be killed" Reproached by the chair at this point he admitted he found himself expanding instead of contracting, but finished pertinently with the remark that the doctor did better work when he need not consider the patient's pocket The amendment was carried The meeting supported a proposal that, whatever provision was made, the principle of payment for medical services (other than those provided by public assistance) should be maintained either through contributory or insurance schemes

STATE SERVICE

A motion by Bromley, Chesterfield, Leigh and Swansea, that the basis for the coordination and integration of health services should be the establishment of a whole-time salaried Government medical service, was hotly debated and then lost by 177 to 20 This was noteworthy because many of the speeches favoured the motion Thus Dr H W Pooler regarded the health centre provided by a statutory authority, discussed in the interim report, as a step towards a complete service Dr J A L Vaughan Jones felt we must plan for both the community and the profession, with the community in the foreground, and that we were moving towards socialisation of services Dr C I Schiff pointed out that any discussion of this topic would have been impossible fifty years ago and barely possible thirty years ago—an indication of changing thought Dr J M Hunter however reminded the meeting that they had already passed resolutions providing that the patient should have free choice of doctor, and that group practice should be arranged by the doctors themselves Neither would be possible, he said, under a state service Dr F M Rose believed a state service to be inevitable in the long run, but Dr D A Ireland said Shropshire was against it Dr Frank Gray shook his head over the doings of Whitehall and asked whether judging by its acts the Ministry of Health was the best body to provide a medical service? He would not vouch for its honesty Sir Kaye Le Fleming reminded the meeting that the salaries in a state medical service would no doubt resemble those in the defence services Doctors would lose their freedom, he said, to be at the mercy of a Government that had never shown any great interest in the welfare of the medical profession Other speakers agreed with him and the final vote was a landslide

THE BROAD PLAN

A motion that the plan in broad outline in the draft report should be adopted was subjected to some manipulative surgery before it was put to the meeting Thus Dr J A Ireland (Shropshire) proposed that it should be adopted only in so far as it related to changes in central and local administrative and advisory machinery His division, he said, wished to see the hospital system pooled and brought together under a regional body The chairman remarked that if the amendment was passed it would rule out health centres Dr Pasmore

MEDICAL PLANNING

CONFERENCE OF BMA REPRESENTATIVES

SEPT 8–10, 1942

Faced with 218 items on the main agenda and a further 36 on the supplementary agenda, the representatives of divisions of the British Medical Association settled earnestly down to work at BMA House on a Tuesday morning If the gathering lacked some of the ginger of the old days, it managed, under the chairmanship of Dr H Guy Dain, to get through this mass of business by the afternoon of Thursday The main debate was, of course, on the draft interim report of the Medical Planning Commission, but it was preceded by one or two topics of interest to the profession at large, as well as domestic items affecting the association

WHO SHOULD PAY FOR THE CMWC ?

Dr Arthur Beauchamp (Birmingham Central) moved that the payment of the Government towards the expenses of the Central Medical War Committee was inadequate The expenses of running the committee had been estimated at £17 000 and the Government contribution only amounted to £7000 The Government, he felt, should give more help At least half the work of the committee was voluntary, and no Government department could do it as cheaply Of course, he added in a burst of frankness, the association would not like the work to pass out of its hands He was supported by Dr W D Anderson who thought the Government grant should be increased and Dr C I Schiff who did not see why the association should bear any of the cost Dr J W Bone, as treasurer of the association, admitted that the grant was not a large one, but said the figure of £17,000 estimated as the cost of running the committee was a generous estimate If the association started bargaining the Treasury might set up its own machinery, and it was to the advantage of the association to continue to make this contribution to war work and to the profession as a whole The Chairman remarked that the treasurer was out in supposing £17,000 to be a generous estimate , the cost of the committee was £21,000 The meeting supported Birmingham's view that the Government should make a larger contribution

DEPENDANTS OF SERVICE MEN

Bristol had sent in a motion expressing dissatisfaction with the reply of the Government about provision of adequate medical attention for the dependants of those serving in the Forces Dr G C Anderson, secretary to the association, said in preface that this need had been repeatedly put to the departments concerned, but the Government was not prepared to make any provision, and had stated two months ago that the subject would not be reopened Dr F H Bodman (Bristol) then introduced the motion , Bristol, he said, was dissatisfied with the Government reply, and was unwilling to let this scotoma at Whitehall go untreated The dependants of civilians had never been so well off in their lives, but the dependants of serving men were forming a new depressed class They were living in furnished rooms instead of homes of their own , the mother had to go out to work, and could not afford either the money to take a child to the doctor or the time to take him to an outpatient department Thus the child's health deteriorated because treatment was delayed and he had seen cases of tuberculosis and heart disease in children which had been neglected for these reasons Service men were indignant about the lack of care of their children , the association should press the Government again The meeting agreed with him

THE SERVANT PROBLEM

No tea-party of suburban ladies ever discussed maids with more feeling than the representative body After some absorbing gossip on "wait-till-you-hear-what-happened-to-me" lines, the chairman invited the meeting to be less domestic Dr F E Gould (Birmingham), who moved that the council should try to secure reservation of at least one maid in each doctor's house and of the doctor's dispenser, pointed out that more women doctors would be able to get on with their profession if there were maids to relieve them at home Dr Anderson's statement that the Ministry of Labour had consented to give special consideration to cases where doctors were experiencing difficulty through calling-up of maids was sniffed at The meeting wanted its maids and dispensers reserved, not returned after an interval of chaos , and it carried the motion Dr Mona Macnaughton (Newcastle-on-Tyne) proposed that doctors' maids should have the same exemption from military and other service as similar staff in hospitals This, she said, would enable authorities to direct maids into doctors' households which they were at present not at liberty to do , the meeting supported her

THE WEALTHY PANEL PATIENT

Dr H E Offord (Reigate) asked the meeting to disagree with the present system whereby high incomed people became eligible for National Health Insurance by virtue of some low-paid employment Total income, he said, should be the deciding factor People with considerable private means are getting NHI benefit through taking some low-paid civil defence or other employment The income of one of his panel patients was £2000 a year He was supported by Dr A Stavely Gough who suggested that a decision should be based on the gross income available for taxation after deduction of family allowances He had on his panel the five grown-up children of a man with a private income of £5000 Dr E A Gregg said that the Insurance Act Committee had already considered this point, which bristled with difficulties , but they were willing to try again and on his suggestion the motion was referred back to the council

Medical Planning Commission

Mr H S Souttar, in presenting the draft interim report of the commission reminded the meeting that it was no more than a draft , and that it was important for the council to know what the association thought about it The Chairman then moved that the meeting should consider the report under several broad heads Two amendments, from Wandsworth and Halifax, that no changes should be decided on until victory was achieved and absentee doctors had come back to speak their minds, were lost The meeting was perhaps influenced by Major R Scott Stevenson, who took the view that those in the Services would resent it if, in their absence *practitioners at home settled the status of the* profession for a generation to come , but they would resent it still more, he said, if the home team allowed some outside body to settle things for the profession Recognising that they would thus be in the doghouse anyway the representatives might well have felt daunted Dr Anderson, however, said that the authorities had agreed to allow any decisions reached by groups of doctors in the Forces to be passed on to the association, and though Major Scott Stevenson remarked gloomily that news of this concession had not so far percolated to *him* the meeting felt encouraged to vote against committing themselves to a policy of unmasterly inactivity

They agreed that, broadly, the objects of our future medical service should be to provide a system directed to the achievement of positive health, prevention of disease and relief of sickness, and to render to every individual all necessary medical services—general, specialist, domiciliary and institutional Motions to remove the word "positive," as having no meaning in the context, were defeated , it was said to have a propaganda value

FREE CHOICE

Many divisions had sent in a motion that free choice of doctor and patient should be an essential feature of any future service An amendment by Bolton that the word "important" should be substituted for essential was moved by Dr H W Bowyer Free choice, he said, was essential as far as administratively possible, but if health centres were set up there must necessarily be some limitation of choice Dr Thomas Craig pointed out that distance was also a limiting factor in choice but Dr J C Arthur was for the word essential, holding freedom in choice of doctor to be parallel to freedom in choice of priest, and one of the liberties of democracy We have even been trying to get some opportunity for choice, he reminded the meeting, for the Poor Law patient Dr A T Rogers thought the word restricting, since rota systems hindered free choice, and yet it might be that the profession would wish to make use of

Industrial Difficulties

Dr MACNAUGHTON said that in her area (Newcastle) the relationship between the general practitioner and the industrial medical officer was not a happy one A subcommittee had been formed to discuss it but without good results since the industrial officers said that the ethical subcommittee of the association had not met since before the war, and that they could not be expected to keep prewar rules She asked that this matter should be referred to council for investigation She was supported by Dr CRAIG Dr BONE said that the rules were certainly being flouted but they had been drawn up with foresight and only small alterations had been necessary These were constantly in the mind of the subcommittee Dr INWALD proposed that general practitioners should be appointed as part-time officers to all factories not employing whole-time officers and that cooperation between the general practitioner and the factory officer should be facilitated At present general practitioners are ignorant of the conditions of work in factories, but much of the population is employed in small factories and general practitioners who had had training in industrial health might give help there Dr WAND said that the committee on industrial health supported this, and the motion was carried

Tuberculosis—Some Other Topics

A long motion put by Dr A PHILLIPS (City) noted with concern the increased incidence and death-rate from tuberculosis and urged the need for wider powers for the provision of financial assistance to patients, so that they should not be deterred from accepting a full course of treatment, and also asked for adequate institutional care The motion attributed the increase to the effect of long hours of work especially on young and immature people Dr Phillips spoke of the difficulty of persuading a father of a family to accept treatment and Dr J A BROWN also emphasised the ill effects of overlong hours The meeting agreed heartily

Dr W B HEYWOOD WADDINGTON (West Sussex) proposed that for negotiation with the Ministry of Health there should be a drawing together of bodies representing existing medical opinion He had in mind the Medical Practitioners Union and the Socialist Medical Association The motion was lost

Dr BARBARA ABERCROMBIE (Liverpool) drew attention to the discrepancy between the cost of oxygen cylinders supplied to garages and those supplied to the medical profession—2*s* 9*d* as against 9*s* 6*d* The matter was referred to council

Dr WHITAKER (Guildford) wanted Whitehall to send on automatically to civilian practitioners the medical history and results of special investigations on men and women discharged from the Forces on medical grounds The meeting shared his wish

Dr H D McILROY (Greenwich) moved that the law should be amended to allow medical practitioners to act as members of local authorities while participating in their medical services The CHAIRMAN pointed out that the medical profession could hardly expect to get a privilege not granted to any other servant of a local authority and the meeting passed to the next business

Sir KAYE LE FLEMING moved that further consideration should be given to the machinery for introducing health legislation The Minister of Health, he said, came into office knowing little about health administration and his chief advisers were out of touch with medical practice The medical members of Parliament, much as he liked them, would never have got there on the suffrages of their colleagues Everyone agreed with him and supported the motion

A motion introduced by the City by Dr SCHIFF was also accepted, it provided that the local medical war committee should take what steps were necessary to secure mutual help among local practitioners—by rotas for night and emergency work, and the like—to meet the increasing strain as doctors are drafted into the Services

The New President

Sir BECKWITH WHITEHOUSE, introduced by the retiring president, Dr T FRASER, opposed a state medical service and discussed the education of students who, he feared, were too materialistic in their standpoint these days He regretted political student societies, and welcomed the inquiry now being conducted by an interdepartmental committee into medical education

In England Now

A Running Commentary by Peripatetic Correspondents

READING your correspondents on the subject of childbirth, I am sure someone should write a popular treatise, or even a novel, describing just *how* unpleasant or painful normal childbirth is Almost everyone seems to have read "Farewell to Arms," in which it emerges as an awful affair and the gas doesn't work Apart from that, male practitioners are always being told that they just can't imagine, and that if men had to have the babies there wouldn't be any But there are other pains which are common to male and female, cannot we be told how labour pains compare with intestinal colic, renal colic or cramp ? If only one could point firmly to a book, or even a paragraph from one of your peripatetic multiparæ, it would be easier to deal with such purely monosexual arguments As it is, the ordinary male doctor has to shy away from the question of labour pains, though for the patient pain is probably the most important point of all It is all very well saying that it is a natural and supremely satisfying experience when it's over, I know I shall feel fine when I leave the dentist's chair, but that's no comfort three quarters of an hour earlier

* * *

The Students' Number started a conversation on the humour of examinations This may not be obvious to examinees, but time's benign therapy lets us see the funny side *Dulce est desipere in loco* "I remember," said the obstetrician, "a man in my class coming lugubriously into the Union, quite sure that he was down in midder since he had completed a question on the management of breech presentations with a detailed account of decapitation of the after-coming head However, he was granted an oral (*Anglice*, vyver, or so it sounds to the Scot) at which the examiner asked him to enumerate the contents of his bag if he were going to a breech case He produced a formidable list, finishing off with a decapitation hook 'And what is that for ?' asked the examiner 'To decapitate the after-coming head,' was the answer—as he afterwards said, forced from his unwilling lips" This recalled to the physician another story about a bag, this time the student being asked to prepare to do a lumbar puncture at a patient's house He also produced a detailed list, and when he was finished the examiner said gently, "Would you not include a syringe ?" "Oh yes, sir, certainly, a syringe, sir" "What sort of syringe ?" "A Higginson sir" When the laughter subsided the surgeon remembered how he had been making very heavy weather of materia medica and had explained that the action of ammonium chloride was to dissociate in the lungs into free ammonia which was a respiratory stimulant, and free HCl which acted as a disinfectant The shuddering examiner had hastily changed the subject to the treatment for an overdose of opium, for which the embryo surgeon had recommended strong tea The examiner agreed, but pointed out that strong coffee was more frequently advised "Yes sir, I know, but the tannin in tea is a precipitant for alkaloids, so I would prefer it" "Good God!" exclaimed the distinguished pharmacologist, "I never thought of that before Did you think of that yourself, my lad ? Excellent!" He got through Then the obstetrician returned with another of a girl who had been up for clinical midder with him, and after she had done fairly well with the examination of the case, the examiner said, "Suppose this were a case of Bandl's ring, what would you do ?" This brought her up short She hummed, hawed and stammered, but produced nothing coherent "Come now, miss, you must make up your mind quickly, if you don't do something immediately the outcome might be fatal" "Please sir," burst out the embarrassed candidate, "I'd send for a doctor"

* * *

The fair, organised by the children for a charitable object and held in the garden, realised £4 3*s* 11*d*, it was a qualified success A tentative suggestion of mine that the proceeds might go to a starving fathers' fund (to which I was willing to act as treasurer) was sternly negatived Instead, I was issued with a seedy topper, a still seedier tail-coat and a badly holed umbrella from the charades trunk and told to guess—and guess accurately—the body-weights of all comers for the absurd suggested that the meeting would like health centres set up but not of the type outlined in the report, which he described as glorified outpatient departments Dr Beauchamp disagreed with this view of health centres, he saw in them a chance for a man to profit by consultation with his colleagues They were hoping in Birmingham, he said, to set up a health centre, this amendment would make that impossible Dr Ireland rescued the meeting from its dilemma by removing the word "only" from the amendment after which amputation it was carried

Dr J C Arthur (Gateshead) asked that the proposals relating to the establishment of health centres should not be approved This led to a useful discussion of health centres, which seem to promise more benefit in towns than in country districts Dr Somerville, speaking from the heart of Midlothian held that while doctors in a country district would not get full advantage from a health centre they would at all events get the chance of consultation with colleagues and the use of laboratory and X-ray services Consultations with specialists could also be arranged at the centre Dr J G Thwaites hoped that the centres would be provided with auxiliary services, including nurses, health visitors, electrotherapeutic equipment, facilities for performing minor operations and a combined dental centre Dr Craig was morbidly convinced that the consultant would be kicking his heels in a health centre when he ought to be working in hospital He thought the whole idea of health centres required years of consideration Dr Wand pointed out that having agreed to group practice the meeting must have ideas about where the groups were to work They would have to have premises and they might as well have the best that could be devised Dr R W Rae said that in Staffordshire they felt that health centres would only be possible as part of a full health service Doctors already had enough equipment for treating patients in their surgeries, radiology should be at hospitals in the hands of experts All the doctors needed was better laboratory help Dr A J McCutcheon (Glasgow) pointed out the advantages of a health centre to the doctor he could live in a smaller house and save on petrol, and he would always have a locum available if he was ill

Dr T W Turner (Guildford) had no sympathy with the lone wolf who felt he could get help only from the pundit He was in favour of group practice in the health centre, and so was Dr H S Howie Wood (Isle of Wight) who remarked that 100% of doctors' wives would be in favour of practice away from the house Dr S W Swindells (Grimsby) thought nothing but health centres would make it possible to take back the care of the children which had been lost to local government services Dr Gough (West Herts) thought the needs of different districts were bound to vary and was anxious that health centres should at first be experimental Dr W N Leak, though attracted by health centres, resisted their glamour because he thought they would lead to too much regimentation Dr Gray brought the meeting back to the broad issue, did they approve of the principle of health centres or not? He had grave doubts himself and thought the scheme set out in the report would be unworkable, but if the meeting approved the principle the commission could get to work and devise a scheme in much greater detail for consideration next year The Chairman believed many would be in favour if they were assured that experimental, not statutory health centres were to be set up No proposals to set up statutory health centres at this stage had been made by any public body Dr Wand suggested the substituted amendment that the principle of health centres be approved which was carried in place of the original amendment A further amendment excluding health centres on a statutory basis from this approval was defeated, as Prof R M F Picken pointed out, if carried it would have eliminated any state provision, yet it was inconceivable that ultimately health centres could do the work now done by local authorities on any other than a statutory basis The plan in broad outline as far as it affected health centres set out in the draft report of the medical planning commission was then approved

A motion by Fife that unification of hospitals under a regional body should be approved, provided unification was confined to general hospitals and that special hospitals were excluded, was lost, the meeting felt that special hospitals and even mental hospitals should rather become part of the general hospitals Dr W Yeoman (Harrogate) moved that all regular medical practitioners should have the right to take part in the national service and should as far as possible have choice as to the area in which they were to serve, not unnaturally he carried the meeting with him So did Dr J A Pridham (Dorset) who moved that agreement to any new scheme for the regulation of medical practice should be subject to equitable remuneration being obtained, and also to adequate and agreed compensation being given for the capital value of practices A proposal from Aberdeen that there should be adequate financial provision for research was accepted without a vote

GOVERNMENT OR CORPORATE BODY?

Two motions were considered together, being mutually exclusive that the central machinery of the medical service should be a Government department, and that it should take the form of a corporate body Dr J H Stephen (Aberdeen) introducing the former motion had a good word for the devil we know Dr Schiff feared that corporate bodies might spring up and interlink, and the power of Parliament would be superseded Guildford, speaking through Dr D F Whitaker, favoured a corporate body, glancing with admiration at the London Passenger Transport Board Dr Pasmore complimented the BBC too, but pointed out that the powers of such corporate bodies were limited by charter and a new charter was needed before any advance could be made This handicapped day-to-day action Moreover, the public could exercise little influence on the deliberations of such a body Dr Gould expressed the distaste of Birmingham for control of the service by the Ministry of Health as at present constituted The ministry had been described as the legitimate child of the BMA, but the child had turned round and taken the bread out of its mother's mouth The local authorities, he added with a brisk change of metaphor, were tarred with the same brush Dr Rae thought the form of committee didn't matter as long as half of it was composed of medical men and Dr R W McConnel brought detailed views from the Bucks division, which was not in favour *of either the ministry or the approved societies as organising bodies* Dr A S Wigfield pointed out that the Minister of Health, owing to his usually short term of office, was handicapped by lack of time, and the civil service by lack of power of independent action, while F W Grant having noted that the ministry had administered National Health Insurance for thirty two years, asked if anyone thought they had made a really good job of it? The meeting rejected the ministry in favour of a corporate body by a large majority Prof Picken remarked that this put the association in an awkward position with Government departments and bound their hands unduly, and after a little shuffling an amendment was carried that the meeting, having expressed a strong preference for administration by a corporate body, referred the matter to council for further consideration

A motion was carried that whatever body is set up to deal with decentralised health, administration should be required by statute to delegate the administration of hospitals and other medical health and ancillary services to a committee or committees composed of (1) non medical members of knowledge and experience in health matters, and (2) medical men in adequate numbers elected from among the medical men in the area

A motion that any medical scheme should be divorced from the control of the approved societies was accepted unanimously A proposal that any interim changes necessary before a complete plan could be brought into action should be so designed as to fit in the plan as now evolving was also passed with little deliberation, as was a proposal that plans for immediate postwar application should include the creation of regional hospital councils with executive or advisory functions Cardiff moved that the conditions of service in any new scheme be the same for men and women and that they should both have equal opportunities of promotion and experience, this was carried unanimously A motion from Oxford providing for hospital beds for the patients of general practitioners, under the new scheme, was accepted

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE House reassembled last week to hear the Prime Minister s report on the war and to transact some urgent business including the voting of another £1000 million for the war and then adjourned again The war debate was a fiasco Mr Churchill's speech did not manage to prevent a number of members leaving before it was finished and during Mr Greenwood's speech for the Labour Party nearly all the rest left to get lunch While Mr R A Cary (Conservative) and Dr Haden Guest (Labour) were speaking there were very few present and when Dr Guest sat down the Conservative Whip moved " to report progress " and the debate ended for the day The House is tired and perhaps it has been sitting too long long over the normal life of any Parliament

But if the House is tired the departments are very busy and the Ministry of Health has been helping the new Ministry of Fuel and Power in the organisation of its projected medical service The orthopædic and fracture service of the EMS hospitals is to be available to all war industries including mining There are 21 orthopædic centres in England and Wales covering all aspects of treatment and rehabilitation from initial resetting to the stages of physiotherapy remedial exercises and occupational therapy About 60 fracture departments in England and Wales are used for cases needing a long stay and others are adapted for cases which only need a shorter stay There are 7 orthopædic centres in Scotland and a number of hospitals with fracture departments The integration of these services in the EMS is to be of great value in the war effort and of permanent value in industry and it is hoped that a full statement will be able to be made when the House meets again after the recess

Another matter which will also claim attention is the treatment of VD cases The percentage incidence of syphilis has increased sharply, over the whole population, since 1939 and is likely to rise further Will it be possible to divorce this subject from any but health considerations and deal with it on its merits as a problem of hygiene If this is to be done there must be more propaganda as open as that for protection against, say, diphtheria which will aim at creating a hygienic conscience in the nation on this matter

The facilities for treatment in every locality must be given more publicity and each local authority should make sure that their area is adequately provided The crucial problem remains of people known to be sources of infection who either refuse or neglect treatment This is a thorny question for Parliament and for the local government authorities but it demands attention in view of the rising incidence of syphilitic infection

QUESTION TIME

Fertility Data

Fertility statistics for 1939 based on material obtained under the Population (Statistics) Act, 1938, have been prepared and will be published in due course under the limited edition arrangements applied to the Registrar General's annual publications Fertility statistics based on the 1931 census returns would normally have been published in a Decennial Supplement volume which was in course of preparation on the outbreak of war The latter statistics are, however, indirect and far inferior to those now obtained under the 1938 Act , and it has not been thought necessary to proceed with the completion of this volume during the war The principal indications afforded by the census material were published in the Registrar General s Annual Review for 1937 (Mr E BROWN replying to Mr IVOR THOMAS)

Diphtheria Immunisation

In reply to a question Mr BROWN stated Information from about 90% of the local authorities whom I have asked for returns shows that in the six months ended June 30 last, out of some 13,400 children notified as suffering from diphtheria about nine tenths were children who had *not* been inoculated, and that in 797 fatal cases there were 780 non immunised children, as against 17 who had been inoculated.

Mines Medical Service

Mr JAMES GRIFFITHS asked the Minister of Fuel and Power what steps had been taken to establish a medical service in the several regions under the reorganisation scheme , and if he would cause an investigation into the effect of diet deficiencies particularly deficiency of fats, upon the health of coalminers —Major LLOYD GEORGE replied Officers of my department with other departments are working out a scheme for a mines medical service, and I hope to be able to announce my proposals shortly The general question of diet is a matter for the Minister of Health, but food in relation to the colliery canteens has been considered by the Miners' Welfare Commission in association with the Ministry of Food and in consultation with high medical authorities

Mr GRIFFITHS Is the Minister aware that in some areas the doctors are concerned about dermatitis which they think is due to deficiency of fat in the diet, and will he bear in mind that unless miners are given adequate food the output is bound to go down ? No further reply was given

Silicosis Report

Mr GRIFFITHS asked the Minister what progress had been made in the consideration of the report of the Medical Research Council on the problem of silicosis , and when it was proposed to give legislative effect to the committee s recommendations —Mr O PEAKE, replied Proposals for action in the direction recommended by the committee have been communicated to the two sides of the industry and discussions are in progress I hope that it may be possible to reach agreement on these proposals at an early date as a basis of legislation

Eyestrain among Industrial Workers

Mr D ADAMS asked the Minister of Labour whether, as visual strain was an important factor in industrial capacity and accidents, provision was made to meet eyestrain and similar ailments in industrial concerns , and whether the services of surgeons and opticians were where required, available —Mr G TOMLINSON replied The main provision made against eyestrain in factories is the requirement of lighting which is both sufficient and suitable For some fine work special lenses or other aids to vision are provided There are no special arrangements for factory workers as such to obtain the advice of ophthalmic surgeons or opticians, but a few factory managements have made special arrangements to assist their workers in obtaining such advice

Mobile Dental Units for Workers

Mr ADAMS further asked the Minister whether he had considered the provision of mobile dental units for industrial concerns —Mr TOMLINSON replied The Minister is aware of the importance of the care of teeth, and the question of arranging for mobile dental units without prejudice to other facilities has been repeatedly considered, but the shortage of dentists has been an obstacle, particularly as it has been felt that existing facilities would tend to be impaired if dentists were called upon to spend more of their time in visiting factories

Addition of Calcium to National Flour

Sir ERNEST GRAHAM-LITTLE asked the Parliamentary Secretary to the Ministry of Food whether, inasmuch as milk is universally recognised as the best source of calcium in the diet and the supply of milk had progressively increased since the outbreak of war, he would reconsider the decision to add chalk to the national bread.—Mr W MABANE replied The Minister is not prepared to reconsider his decision to make some addition of calcium to the National Four While the overall consumption of milk, which is the most desirable source of calcium, has increased since the outbreak of war the intake of calcium per head of the population prior to the war was abnormally low I would refer to the report by the Medical Research Council, published in the medical press in May, 1941

Wheat Germ in Proprietary Medical Products

Sir E. GRAHAM-LITTLE asked what proportion of the wheat germ separated from the grain in milling had been allocated, in accordance with the confidential instruction CMC 191, (30/4/42), during the past three months to proprietary products, whether foods or medicines, and to be at the disposal of the millers in the ordinary way of trade, respectively —Mr MABANE replied During the last three months more than 99% of the output of germ not retained in fee of threepence a time Unless my guess was correct to within 3 lb I received no fee at all Despite many gross and humiliating blunders I contrived to clear up about five bob, but had I been called upon to disburse threepence every time I made a mistake I might now be in the hands of the Official Receiver The skittle-alley (roll, bowl or pitch) and the cockshy both made good money and so did the bagatelle board, though we dropped a packet—half a crown, in fact—on a game which consisted in throwing pennies on to the black squares of a chess board, too late we realised that we hadn't made it difficult enough and that the money prizes were too high But the air-gun shooting at very small targets and pendent apples was almost impossibly difficult and here we took eight and fivepence The numerous and costly but almost unringable gifts at the hoop-la table attracted plenty of custom, and fortune-telling, at fourpence a time, was a bargain not to be missed Here it was interesting to observe how cheerfully many a mature and happily married matron reacted to the news that she was to be married again, perhaps three or four times Hope springing eternal, I suppose The largest single source of revenue, excluding perhaps the sale of synthetic lemonade and a terrible pink drink that looked like Red Biddy at 2½d the glass, was unquestionably pony-riding For twopence you could have a hundred yard hack on the large bay, and, for a penny, a shorter but perhaps more exciting ride on the small black who was a bit on the fresh side The children fairly queued up for these Each had to be lifted on and held firmly in the saddle, and when lifted off at the end of a ride merely rejoined the queue It began to look as though it would never end, but providentially the rain came, during which I was able to escape and recruit my exhausted energies in the comparative peace of evening surgery

* * *

We have lived through a ten days' terror, for it is just that time since a misguided colleague suggested that our medical staff could produce something better in the way of concerts than many we had experienced The spirit of emulation everywhere leads to trouble and our concert threatened to bring full measure of that There must have been something in the air on that night of ill-fated decision, for though some of us, the more balanced majority, knew well the dire peril towards which we were heading no determined voice of protest was raised Only one of our colleagues expressed serious doubts, and these arose not so much from principle as from consideration of the part in which he seemed likely to become involved, a part so light and elfish that he thought it in ill-accord with his sedate respectability, for would his wife approve of a project that featured him as the father of a ventriloquist's doll, none other than one of our petite lady house-surgeons? But his fears were groundless, for providentially the lady decided to marry on a date which rendered her return in time for the concert scarcely decent, though she did offer to interrupt her honeymoon, so the ventriloquistic act had to be deleted, possibly to the edification of the body politic

It was decided that every member of the staff must contribute to the programme, that there should be an opening chorus and a finale with all on the stage, and that each of the items constituting the body of the programme should be the individual concern of one member of the staff, who would be responsible for rehearsing his own little piece and bringing it to final rehearsal ready for presentation That was the theory Suggestions for the several turns were considered in the broadest of broad outline and the conspirators retired to their several dens to write the chapters of the book The days passed and weird knots of medical people were to be heard making ill-assorted noises, with all sorts of weapons in all sorts of corners Two days before the concert was due we gathered for a rehearsal It was awful! The individual items were diamonds in the rough and the whole as a composite effort beggared description Then there emerged, as usually happens, one who was chief among us He marched us up and marched us down until many felt that life would never be the same again, that concerts were an invention of the devil and that this particular son of the devil who had the mania for rehearsing should be suppressed For 3½ hours we rehearsed a 90-minute show on that wretched evening, and on the day before the concert we returned to the charge This time things were better It began to look as if after all some order might be evolved from the chaos, though the rehearsing demon was still far from satisfied

On the actual night of the concert we fortified ourselves, each in his own way, and half an hour before the curtain we went apprehensively to our dressing-rooms to acquire our fine raiment and to have applied those deft touches that are supposed to make the finished artiste We started right on time after a last minute argument with an obstinate curtain which seemed determined to make a dying effort to save us from our folly There was a burlesque medical board, showing from the inside how these things really happen and how glamour can oft deflect the course of justice, and an enterprising effort by an accomplished salesman anxious to interest a passer by in the merits of a patent mousetrap There were songs grave and gay, some topical, with all the makings of trouble There was the mixed tale of a radio whose knobs went wrong, and there was a Brains Trust with a quota of eminent physicians far outshining any of their less illustrious contemporaries in dealing with a wide variety of questions that gave free rein to many shrewd barbs Questions were invited from the audience, but it was found expedient to ignore these, it is understood that that sometimes happens even in the best Brains Trusts Then there was a lecture on his travels by one of our travel-stained veterans, who outlined his crazy path through darkest Africa, having invoked the assistance of a colleague of artistic soul to draw for him illustrative lantern slides that had to be seen to be believed—slides with the most gorgeous, decrepit camel duly vaccinated, the most prehistoric bicycle in all dark Africa, and a hitch-hiking monkey that was the lecturer's constant and devoted friend There were lightning sketches by the artist in person and there was a wonderful closing chorus featuring some of those songs of the west that seem to be everywhere these days, with a shooting up of the villain and the emergence of a triumphant if breathless and horseless sheriff, the costumes for this final blaze of glory were procured with some difficulty and the connivance of the local boy scouts What appeared to afford the audience most merriment was the opening chorus, with its dresses made on the premises, featuring the entire medical staff attired as VADs might appear in their raiment of office The first appearance on the stage of this pseudonursing serpent sent the audience into a convulsion from which it never really recovered, and it was only afterwards that we learned that the prime causes of their laughter were effects altogether unrehearsed—the most friar-like of the brethren had come apart at the back and looked rather more like a prosperous butcher than a down-trodden nurse, while the physician, who later in the evening sang a sad tale of one Donald who took to golf, appeared in this opening chorus in concertina stockings, which earned him lasting disgrace Self-conscious nurses came unstuck in all sorts of impossible places The carefully rehearsed words of the chorus never reached the pianist, much less the audience, and the whole thing was a glorious fiasco which somehow set the seal of success on everything that was to follow But there will never be another doctors' concert if we can help it

* * *

At the end of an outpatient sitting I often wonder what it is that the doctor really does say to his patient First came Mrs Jones, sent up by Dr A, whom I know well as a man who loves the English tongue and chooses his words with care She described to me how she felt icy cold in spite of the fact that she was hemmed in by a little wall of fire no more than a foot high, and how her two kidneys, as she lay on them, felt like two great white slugs under her ribs Then she went on, " And I sez to Dr A, I sez, ' Doctor, what shall I eat? ' and 'e sez to me, ' Mrs Jones, you make a sack of your stomach and pop into it just what yer fancies! ' " Next came Mrs Peabody whose doctor had " told her straight " that it was the shock of her poor husband leaving her that had opened one of the valves of her heart and that nothing but the grave would close it Finally Mrs Beadle gave me this graphic but apparently second-hand account of her cystitis " Me doctor 'e sez to me ' Mrs Beadle, yer bladder's gorn and there's nothing but the strings of it left ' " I wish the doctors would put their picturesque phrases straight into the letters they send up

Letters to the Editor

POST-ARSPHENAMINE JAUNDICE

SIR,—In your annotation of Sept 5 (p 287) you say "It is reasonable to suppose that many cases of post-arsphenamine jaundice are due to virus infection, the resistance of the liver having been impaired by the toxic action of the arsphenamines "

Early in 1940, when I was assistant pathologist to the LCC Whitechapel Clinic for the Treatment of Venereal Disease, I began an investigation of jaundice occurring in patients undergoing treatment for syphilis The period under review was from June, 1930, to Dec 31, 1939, which was later extended to include 1940 In this period there attended the clinic over 3400 cases of syphilis, of which over 2200 received arsphenamine Among these latter between 260 and 270 patients developed jaundice For the purposes of this investigation post-arsphenamine jaundice was defined as that occurring within not more than three months after the last dose of arsphenamine It was found that 90% of cases of post-arsphenamine jaundice occurred within 4–6 weeks after the last dose of arsphenamine An analysis of the results in terms of (*a*) number of grammes of arsphenamine actually administered before jaundice appeared, and (*b*) the length of time during which arsphenamine had been administered, showed that 6–8 g of arsphenamine given over a period of 10–13 weeks produced the highest percentage of jaundice It should be pointed out that of any given number of patients starting treatment for syphilis only a fraction actually continue steadily receiving arsphenamine, which means that the number of patients receiving 6–8 g of arsphenamine is very much less than those receiving 1–2 g , yet the absolute and percentage incidence of jaundice in the higher dosage levels is greater than in the lower

It is well known that there is a lag in the excretion of arsphenamine, so that if the drug is given continuously every week there must occur a gradual increase of arsphenamine in the liver Post-arsphenamine jaundice is a function of two variables—the virulence of the virus of infectious jaundice and the extent to which the accumulation of arsphenamine has rendered the liver susceptible to the virus That the part played by arsphenamine is important is shown, I think, by the existence of what may be called an optimum dosage and duration of arsphenamine and by the fact that the incidence of jaundice was evenly spread over each month of the period under review, whereas pure infectious jaundice has a seasonal incidence It happened at the Whitechapel Clinic that in January, 1937, there was a change in the methods of treatment Whereas previously 7 5 g of arsphenamine had been given in a period of 13 weeks, after January, 1937, each patient attending with syphilis received (or was intended to receive) 13 g of arsphenamine in 13 weeks If jaundice is partly due to the accumulation in the liver of injected arsphenamine then patients receiving the latter amounts of arsphenamine should show a greater incidence of jaundice In fact while until the end of 1936 the average incidence of jaundice had been 7–8%, in the years 1937, 1938, 1939 and 1940 the incidence was between 25% and 30%

All the figures I have quoted are from memory, as the records and a thesis based on the records were destroyed by fire due to enemy action in May, 1941, and my duties since that time have prevented my repeating the investigation

London, E C 2 F R CURTIS

LIFE CYCLE OF THE THREADWORM

SIR,—In your issue of Sept 12 Dr Orme cites an instance in which, on the third day of a visit to relatives, one of two Eurasian children in the Malay States experienced for the first time intense anal irritation, while next day both showed numerous threadworms in their fæces He suggests that the visitors became infected from the children of the house (who *had heavy* infections and were inveterate nailbiters), he cites the textbook statements that these worms reach maturity in a fortnight, and he believes that this statement needs reconsideration

Of this parasite T Spencer Cobbold (Parasites, London, 1879) wrote thus "Prof Leuckhart and three of his pupils courageously infected themselves by swallowing eggs and had the satisfaction of observing young oxyurids in the stools fifteen days later " Cobbold then pointed out that these eggs may be found in the margins of fingernails and added, "One aristocratic person, who was infested with myriads of these entozoa, confessed to me that in his extreme distress and consequent rage he had freely bitten the live worms in halves between his teeth " But, as was the case with one of the children cited by Orme, there need be no such extreme reaction from an infection which is common, as the following two instances show Using the NIH swab these eggs were found in 41% of 2097 white children in Washington (*Lancet*, 1939, i, 1167) My own experience of prisoners admitted to a district jail in Bengal is that in every instance in which thymol was given for any reason, threadworms were later found when fæces were adequately examined, and that their hosts accepted in ignorance and with equanimity the presence of what were in practice symbiots Evidently the degree of irritation experienced by the host depends in part *at least* on his own temperament , absence of infection may not be accepted on the ground of absence of local irritation but only on absence of disclosure of infection in adequate fæcal examinations, for instance by the NIH swab Failing this control before and after experimental infections, a latent period of less than a fortnight has no firm basis

Ealing CLAYTON LANE

TOTAL MEDICINE IN TOTAL WAR

SIR,—We are much interested in the questions raised by Mr Franklin (in your issue of Aug 29) concerning the better use of medical personnel, and we would like to endorse his views Doctors who like ourselves work in civilian hospitals with EMS beds are until they go into the Army constantly treating Service patients When they are called up the majority cease to do so Instead many of the Service sick are referred back to the very hospitals where the doctors now referring them were once treating them Possibly because the general practitioners are also short of assistance owing to military demands, the civilian work in these hospitals is increasing and with each further depletion of staff the increase is more difficult to meet We understand that in their new sphere the doctors are more profitably employed with prevention, but those who remain in the civilian hospitals spend sufficient time treating cases unsuitable for preventive medicine to cast doubt on whether the distribution of labour is a fair one The doctors are called up but the patients remain

We agree with Mr Franklin that a unified medical service would have avoided a great deal of the duplication that occurs with several separate systems, but even now that these systems are established we believe much could be done to economise in medical staff We wonder whether it would not be possible to arrange for the temporary return to civilian work of members of the RAMC who share with the rest of the Army the periods of military inactivity inevitable in war We wonder whether soldiers with minor ailments could not have provision made for them other than that of blocking beds needed by urgent civilian cases We wonder whether the military and civil interests could not be coordinated to allow of a fuller use being made of the medical personnel of both in districts where a disproportionate amount of work is falling on one

Some of the undersigned will shortly be called up If we regard this with misgiving it is not because we are less anxious than others to pull such weight as we can but because we are not confident that we shall be doing so On the one hand we see our friends now in the Services not fully occupied , on the other we see those left behind are already working 14 hours a day Outpatient clinics are lasting 5 hours at a stretch and are well past the limit of maximum efficiency Further air-raids may find the staff of the civilian hospitals exhausted and yet it is *upon them that the* treatment of all civil and many military casualties will fall

M BIRD M P SHORT
M M C LOUDEN K STAYNES
London M MIDDLETON

flour has been used in proprietary products, either foods or medicines Less than 1% which for reasons of quality was not acceptable for these purposes, has been used in other ways

Pasteurisation of Milk

The responsibility for distribution of milk rests upon the Minster of Food and at present some 70% of the milk supply is pasteurised before distribution to consumers It is anticipated that the rationalisation of wholesale and retail distribution now being undertaken will result in a larger proportion of supply being pasteurised (Mr Mabane replying to Mr David Adams)

War-time Nurseries

Replying to a question Miss F Horsbrugh said The number of war time nurseries operating at Aug 31 is 826, with 34,000 places From the latest return the attendances are approximately 70% of the accommodation provided The staff employed is approximately 7000, including young girls of 16 and older women resident in the districts It is estimated that some 30,000 women could be freed for work of national importance by the nurseries now in operation Complete figures of cost are not available but it has been estimated that the average would be 3*s*–4*s* a day of which mothers pay 1*s*

Notification of Scabies

Mr Evelyn Walkden asked the Minister of Health whether, since the issue of the White Paper, he had given further consideration to the question of making scabies notifiable in view of the opinion of many local authorities that this course would be of material help to them —Mr Brown replied I am advised that it would not be appropriate to make scabies notifiable generally but I am prepared to consider applications from local authorities to have scabies made notifiable in their district, upon being satisfied that the authority have adequate facilities for diagnosis and treatment

Mass Radiography

Sir Francis Fremantle asked the Minister of Labour if he was aware that of 300 consecutive cases of pulmonary tuberculosis admitted to a sanatorium from the Services it was considered that 200 could have been detected at the initial medical examination by the adoption by medical boards of mass miniature radiography as a routine procedure, and if he would now state the position as to the introduction of this method into the practice of medical boards —Mr Ernest Bevin replied I am aware of the analysis I am, however, informed that perhaps half of those 300 cases were examined by civilian medical boards before the adoption in November, 1940, of improved methods of detection of pulmonary tuberculosis It is considered impracticable to establish the method of mass miniature radiographical examination at the medical boards throughout the country —Sir F Fremantle Has the alternative method been pursued of having centre for the examination of these people ?—Mr Bevin I understand that the Secretary of State for War and the other Service Ministers are carrying out the policy announced by me on April 30 —Sir F Fremantle That is to say that the men already in the Services qualify for a great deal of trouble to themselves and the Services afterwards, and cannot we do something to prevent them getting into the Services ?—Mr Bevin I am sorry, but I cannot introduce the system into every medical board in the country that is absolutely impracticable Therefore, the alternative method of detection immediately they have been enlisted has been found to be the most practical way of dealing with the subject

---

SIGNS AND SYMPTOMS OF DEFICIENCY DISEASES

The third scientific meeting of the Scottish Group of the Nutrition Society was held at Gleneagles EMS Hospital, Perthshire, on Aug 26 Prof V P Sydenstricker (USA) described the clinical patterns which may be associated with deficiency of the B group of vitamins He pointed out that the requirements for certain of the B group of vitamins are definitely dependent on the composition of the diet and that synergistic reactions probably further condition the requirements Vague malaise, weakness, lassitude, nervous irritability, mild depression, muscle pains, anorexia and consciousness of disturbances of gastro-intestinal motility, are early symptoms common to all group-B deficiencies Later, physical signs develop into fairly definite patterns All symptoms and physical signs resulting from dysfunction or degenerative changes of the peripheral nerves and heart are attributed to thiamin deficiency Certain dermatoses and lesions of the mucous membranes and symptoms referable to the cerebral cortex and mid-brain are thought to depend on depletion of nicotinic acid Other changes in the skin and mucosæ and a variety of disorders of the visual apparatus respond to treatment with riboflavin In addition to these there are certain dermatoses and ocular disturbances which respond only to treatment with the entire B group

Dr John Yudkin (Cambridge) reviewed the diagnostic criteria of vitamin deficiency in relation to recognised diseases of unknown ætiology and obscure signs and symptoms He pointed out that the available tests could be divided into those which demonstrate the existence of deficiency and those which show that deficiency is the cause of the condition There are four stages in diagnosis—indirect evidence of deficiency direct evidence of deficiency, the presence of signs to be expected in deficiency, and the cure of the condition by correction of the deficiency

Dr T R Mutch (Aberdeen) gave an account of vitamin-A deficiency in relation to the eyes He pointed out that although vitamin A appears to be related to regeneration of the visual purple, neither the extent nor the rate of dark-adaptation, in his studies, bore any close relationship to the vitamin-A content of the diet Since the introduction of war-time restrictions on diet there has been no increase in the amount of night-blindness, while chronic blepharo-conjunctivitis and corneal ulceration have become less common On the other hand, there has been an increase in the number of infants showing severe photophobia, a condition which readily clears up on improvement of feeding and treatment with cod liver oil and ultraviolet light

Mr John Gerrie (Aberdeen) described the value of vitamin A in the treatment of nasal sinusitis of children, a condition which appears to be on the increase The older treatment by weekly antral lavage is unsatisfactory, for in 60% of the cases suppuration recurs after apparent recovery Vitamin A given to cases with suppuration did not seem to influence the infective process, but it seemed to be highly effective in the pre suppurative stage A number of non-suppurative cases in which the typical thickening of the antral lining had been confirmed by X-ray examination were given vitamin A by mouth or by intramuscular injection and after one to six months only about 20% showed suppuration, while 80% of a group of similar control cases treated without vitamin went on to suppuration

Prof Noah Morris (Glasgow), discussing vitamin D deficiency, said that the classical type of rickets with its well-marked skeletal deformities has almost entirely disappeared in this country, but has left in its place a form of disease which is possibly more dangerous because it is not obvious Formerly, the earliest manifestations of rickets were thought to appear about the fifth month but now it is known that rickets may occur in the fœtus if the mother is suffering from calcium and vitamin D starvation He pointed out that while osteomalacia is most commonly associated with pregnancy and lactation, it may also be produced where there is insufficient intake or poor absorption of lime The non-pregnancy type may often involve the spine alone and is apt to be diagnosed as rheumatism Tetany may occur and there is often weakness and stiffness especially in the adductor muscles of the thighs

Dr Alexander Lyall (Aberdeen), in a paper on calcium and phosphorus deficiency and hypoproteinæmia, pointed out that primary nutritional disturbances of these types are very rare Nutritional hypoproteinæmia is infrequent, but may be associated with anorexia or pregnancy and sometimes with imbalance of chloride and fluid

Prof L S P Davidson (Edinburgh) reported an investigation he had carried out in Edinburgh on the hæmoglobin values in infants, children and pregnant women, and compared the results with those found in a similar investigation in Aberdeen a few years ago

Prof Henry Dryerre (Edinburgh) gave a lecture on deficiency diseases encountered in veterinary practice unted his pulse and was puzzled to find it only thirty le said nothing but went to the other side, only to find le same rate there The patient smiled at her and said, It is all right, nurse, in my case you add them both gether "

Mr Warren Low married in 1902 Mabel, eldest aughter of John Ashby, JP, of Staines, who survives im with two daughters and four sons

HUGH WOLFE CORNER

F C, M D ABERD, F R C P, ACTING GROUP-CAPTAIN R A F

THE death is now presumed of Group-Captain Hugh orner who has been missing since April 25 He was orn in 1898 and during part of the last war he served s a lieutenant in the Cameron Highlanders in France le graduated without loss of time om the University of Aberdeen 1922, and entered the Royal Air orce two years later He was ent to Iraq in 1925, where he erved for three years On his eturn home he was posted to ranwell Hospital, where he qualied as a pilot and in 1929 obtained is MD In 1933 he returned to raq for a further two years Then he came back he held a umber of appointments mostly dministrative, until he was posted n April of last year to headquarters of Fighter Command, for pecial duty in connexion with ying personnel and he was killed while flying on active ervice This last appointment gave Corner the opporunity to exercise his keen and critical mind in an nvironment which he loved, and he felt he had found is true vocation He was a keen pilot, particularly ond of high-speed, single-seater aircraft, and his enthuiasm for flying and profound knowledge of the practical roblems of aviation medicine made him an ideal nedical adviser for pilots Helpful and unassuming, harming and ever youthful he was the friend of all, but articularly of the men who fly

ERIC MACE FOSTER

M B BIRM, LIEUTENANT R A M C

Lieutenant E Mace Foster was accidentally drowned near Tobruk last March He was born in 1918, the son of Mr S Mace Foster of West Bromwich, and was educated at Wolverhampton Grammar School and the University of Birmingham He won many prizes as a student and when he graduated with honours in 1940 he was awarded the gold medal for clinical medicine He was then house-physician at the United Hospitals to Dr Oscar Brenner who writes · "Eric Mace Foster was a quiet, reserved, modest young man, but his obvious ability soon attracted his teachers' attention and interest His keenness and enthusiasm were a pleasure and a stimulus to them, for he approached his clinical work in the scientific spirit and was not readily satisfied with facile and superficial explanations His ready sympathy and human understanding gained him the respect and affection of his patients, his colleagues and the nursing staff" When the heavy air-raids on Birmingham began Foster was chosen to accompany patients to an emergency hospital outside the city and here he remained as house-surgeon and MO in charge of the ENT department until he joined the RAMC in July, 1941. He was sent overseas in January as deputy senior MO to a large troopship and on reaching the Middle East he was attached to a field ambulance

Notes and News

THE ATMOSPHERE OF BATTLE

THE Victoria Medico-Legal Society, now ten years old, has published a limited edition of its last three years proceedings (Melbourne Brown Prior Anderson Pty), containing nine lectures given to the society, seven by members They fall a little short perhaps of the average standard of lecture published in our own *Medico-Legal and Criminological Journal*, except for a refreshing original article from Sir Frank Egglestone, now Australian Minister to China ; his scholarly analysis of the social values of modern legal inquiry is a criticism of the atmosphere of battle in the courts in which cold scientific deduction and strict impartiality are bound to suffer It is summed up in the famous dictum of Mr Justice Maule

> Gentlemen if you believe the evidence of the plaintiff in this case you will no doubt find for the plaintiff If on the other hand you believe the evidence of the defence you will no doubt find for the defendant But if, like myself, you believe the evidence of neither God help you all Gentlemen of the jury you may now consider your verdict

Social progress deserves a more strictly impartial mode of legal inquiry and Egglestone sets out a design for its construction

---

PRIORITY MILK, EGGS AND SOAP —The Ministry of Food has designed a composite medical certificate (R G 50) to take the place of the existing three separate ones for priority milk, eggs and soap, and also to provide for possible extensions of priority rationing The schedules of qualifying conditions still apply, and the doctor is asked to indicate clearly under which schedule a patient qualifies for each commodity No period or quantity need be stated, for the previous maxima are now standard The certificate has places for priority national dried milk and dried eggs, but these are for future use, as is section iii *d*, which will cover priorities as yet undreamt of outside the ministry The new certificate can now be got at Food Offices, but stocks of the old sort should be used up first

Royal Free Hospital

The A M Bird postgraduate scholarship in pathology has been awarded to Dr Frances Bosanquet

Shortage of Rubber Gloves

The sale of household rubber gloves has been restricted to people who are certified by a doctor to be suffering from long and intractable eczema, cheiropompholyx, or intractable dermatitis, and to need rubber gloves for the performance of their household duties

ANÆSTHETIC MORTALITY

SIR,—May I make a constructive suggestion to lessen what many people have an uneasy feeling is an avoidable mortality-rate As long ago as 1910 a Home Office departmental committee issued a report containing certain recommendations which have never been implemented, though it seems impossible to find an adequate reason for this neglect Before any real improvement in mortality figures can be expected some means of recording these fatalities must be arrived at Years ago I put before the council of the Association of Anæsthetists a proposal that, where a death under anæsthesia or within an hour or two of operation occurred in any voluntary or municipal hospital, the matter should be reported to a small committee consisting of a physician, a surgeon, an anæsthetist and a pathologist This proposal did not, however, find favour, as it was found that we were up against the Coroners Act—which many of us think is long overdue for reform Can nothing be done to stimulate medical and public opinion in this direction ?

Liverpool **G F RAWDON SMITH**

THE MUNICIPAL SANATORIUM

SIR,—*Your peripatetic correspondent* of Sept 5 seems to have been unfortunate in the municipal sanatorium he visited and somewhat hasty in the generalisations he makes As medical superintendent of a county-council sanatorium I can say that here are over 100 patients having collapse therapy out of just over 200 , that each patient has her own thermometer and takes her own temperature, that routine instructional talks are given, besides individual talks , that occupational therapy is regularly carried out under a trained instructress ; and that a first-class thoracic surgeon visits here at least once a week for operative work A dentist and an ENT surgeon also visit regularly. This is only one of a considerable number of municipal sanatoria personally known to me where such work is being done

Pinewood, Wokingham **WILLIAM C FOWLER**

SIR,—Delightful as the commentaries of your peripatetic correspondents are, I cannot allow the prerogative of the pulpit to the gentleman who wrote about *Walking Miracle* and the " Balliol of sanatoria," much as I admire the latter Municipal sanatoria as large or larger than Midhurst have no reason to fear comparison with private institutions I know many, besides the one in which I work, in which the standard of treatment is excellent Perhaps, though, if we could give each of them a private income, we should be even more successful in teaching our patients " how to live "

One word more Where do these sweeping condemnations of the tuberculosis service spring from ? Surely from something less than adequate knowledge Perhaps your correspondent would like to see a *second* municipal sanatorium I should be glad to show him what is done here

Colindale, N W 9 **J V HURFORD**

*** Other correspondents have expressed a willingness to supplement our peripatetic's neglected education — ED L

RECOVERABLE SCHIZOPHRENIA

SIR,—In your issue of Sept 5 Dr Sargant agrees with Dr Hemphill that convulsive therapy is not a satisfactory treatment of schizophrenia and cites the experience of the New York State Hospital where a thousand schizophrenics treated with convulsive therapy did even worse than an equivalent control group left untreated And there is much more in condemnation of the method If it is suggested that insulin has been superseded by convulsive therapy I heartily agree with Dr Sargant that general acceptance of this view would be disastrous for the patients concerned I have for many years advocated the use of insulin combined with histamine

Salisbury **HORACE HILL.**

THE *Notes on Essential First-aid* by Brigadier E M Cowell, referred to in our leading article of Aug 22 (p. 221), was originally printed for private circulation only, but copies can now be obtained, price 6d , from Couldrey & Co Ltd , George Street, Croydon, Surrey

Obituary

V WARREN LOW

CB, MD LOND, FRCS

NEWS of the death in London of Mr Warren Low on Sept 2 in his 75th year will have brought a pang to many hearts To the St Mary's school into which he had grown as teacher, surgeon and governor To the College of Surgeons who made him a vice-president, and the many other professional bodies to which he gave whole-hearted service To those who came to rely on the judgment, both as surgeon and man of affairs, which enabled him to make the correct choice without loss of time To numberless others just passing by whose heart was beguiled without their knowing

Vincent Warren Low was born at Staines in 1867, was educated at Cranleigh, and entering St Mary's took all available scholarships and qualified in 1892 with distinction at the BS exam Before climbing the customary tree to the surgical staff at St Mary's he filled a long series of children's appointments at Great Ormond Street and volunteered for the South African War where he won the Queen's medal and was mentioned five times in dispatches, and where he contracted the dysentery that led to the crippling arthritis of which he was never heard to complain On his return he was elected assistant surgeon to the Great Northern and from 1902 he served his allotted term as full surgeon to St Mary's, on retirement being awarded the rare compliment of a hospital vice-presidency. He was a sound surgeon, preferring safety to brilliance, and showed great skill in diagnosis and discernment in treatment, qualities which stood him in good stead as consulting surgeon to H M Forces in the Dardanelles and Egypt 1915–16 when he held the honorary rank of colonel AMS This work gained him the CB

Cotz

Low was elected in 1916 to the RCS council and his work for the college gave him much satisfaction . in 1925 he was re-elected for a second term during which he held a vice-presidency for a decade In 1914 he joined the Society of Apothecaries, of which he became junior warden, never missing a meeting of the court His faithful attendance at medical societies inevitably led to his becoming president of the Royal Society of Medicine and also of the Medical Society of London He was an excellent committee-man and for many years served on the senate of London University and on the council of King Edward's Hospital Fund for London He enjoyed examining for several universities and examinees almost enjoyed his humorous quizzing

Summing up Low's humanity one of his friends writes of him as the ideal good companion ; he loved a chat and delighted in telling a good story At the quarterly court of a benevolent society he presided from the hearth-rug rather than from the chair and preferred to spot the *mot juste* of others rather than say it himself Another writes of his discriminating judgment in the matter of food, both of the mind and the body His taste in literature centred in memoirs and modern history , he was not interested in thrillers or the lighter forms of fiction He was critically interested in art, in which no doubt he was influenced by his gifted wife, a painter of eminence He was an expert of the cellar and the table, not because he was a gourmet, his wants being simple, but to give pleasure to his friends On public occasions he showed great powers as a host For many years he arranged the annual dinners of his medical school, and also those of the RCS council dining club He was a witty after-dinner speaker when his prodigious memory of bygone exploits was often a surprise to their perpetrators A keen mason and past master of his hospital lodge he was in 1929 appointed past grand deacon of the grand lodge of England The irrepressible humour which had so often relieved dull routine did not fail in his last illness A probationer

ORTHOPÆDIC SURGEON TO WALTON CITY HOSPITAL, LIVERPOOL, AND BOOTLE GENERAL HOSPITAL

THIS paper is based on experience gained over a period of 8 years, during which over 200 fractures of the shaft of the femur have been treated, most of them at Walton City Hospital, Liverpool. The method which will be described is that of fixed skin traction using the splint devised by Hugh Owen Thomas. This method has produced a high standard of functional result.

In the treatment of any fracture the method which is ultimately decided on as the best is the result of a compromise by the surgeon in an attempt to achieve the maximum degree of each of the following: accurate reduction of the fracture; immobilisation of the fragments; maintenance of function of the limb until the fracture has united. Taking fractures as a whole, there seems no doubt that, other things being equal, those fractures which are most accurately reduced will produce the best functional result. Trauma by treatment, however, while producing an excellent anatomical position as demonstrated by X rays, may introduce some additional complication which reduces the functional value of the result.

In treating fracture of the femur, surgeons during the past few years have sought to achieve full length in the limb by means of positive skeletal traction applied either to the upper end of the tibia or to the lower end of the femur. Excellent anatomical reposition can be obtained by skeletal traction, but often only at the expense of stiffening of the knee. In any method of treating this fracture the surgeon's main difficulty in the later stages is that of knee movement. In my opinion the method to be described offers the quickest return of useful knee movement coupled with adequate anatomical reposition. In patients up to about 20 years, there is little difficulty in achieving full length without prejudicing the return of knee movements. The difficulties are greater in those muscular healthy men between the ages of 20 and 55 in whom it is not easy to achieve full length without producing a degree of stiffness of the knee which may take many months of treatment before movement reaches 90°. Too much importance has been attached to the achievement of full length; in recent years surgeons have even been encouraged to distract the fragments sometimes, thus producing non-union.

Treatment of a fracture of the shaft of the femur, entirely apart from anatomical reposition, must be regarded as unsuccessful if knee movements have not reached 90° within 12 months, and it should only be regarded as successful if that degree of movement is achieved within 9 months; 90° of knee movement is chosen as the arbitrary dividing line between success and failure because it is the amount of movement necessary for a working man to climb ladders and steps. Provided in the end the patient has at least 90° of knee movement the amount of shortening, if less than ¾ in., is relatively unimportant. The limp resulting from shortening of the femur up to ¾ in. can be overcome by a shoe or boot with a raised heel.

TECHNIQUE

Anæsthesia.—Full relaxation of the muscles of the injured limb is essential, so that the fracture may be reduced and length obtained at the earliest possible moment. The method is used to maintain reduction carried out during the anæsthesia and not to produce slow reduction of the fracture by traction. My preference is for spinal anæsthesia, but in cases where the patient is in a state of shock open ether is probably the best form of anæsthetic.

The Thomas splint.—Since Thomas first described his original splint there have been numerous modifications and "improvements," none of which is as good as the original Thomas, with its fixed ring at the upper end and its wrought iron sides. Spring steel and expanding sides or ring give no advantage. It is of course necessary to have a fairly large selection of different sizes of splints, but an exact fit is not necessary in every case. The relationship of the upper ring of the Thomas to the bony pelvis is important. Counter-traction must be upon the ischial tuberosity, and the relationship of the inner posterior segment of the ring must be carefully maintained in respect of that bony part. In general, the ring is kept in position by the accuracy of the fit to the outer side of the thigh, and where the ring is only a little too large apposition may be maintained by a cotton-wool pack between the outer anterior part of the ring and the skin of the thigh about 1–1½ in. distal to the anterior superior iliac spine. An alternative method of maintaining the ring in its proper relationship to the tuber ischii is by the use of the Balkan beam with a weight and pulley attached to the anterior part of the ring so that it is lifted from behind on to the ischial tuberosity. If a ring which is much too large has to be used, the Balkan beam, weight and pulley method is the only one which will maintain the ring in its proper position in relation to the ischial tuberosity. Should the ring for any reason slip into the perineum, the point of counter-traction is changed, shortening is produced, increased tension of the traction tapes is extremely painful, and nursing care more difficult to carry out. The buff leather covering the felt around the ring becomes dirty after being used on a case, and may be softened by massaging with castor oil. 'Sorbo' rubber padding is not an improvement. The distal end of the splint should project ideally about 6–8 in. beyond the patient's foot, but there is no objection to variations in length between 5 in. and 9 in.

Preparation of the leg.—The limb is washed, shaved, cleaned with ether or spirit, dried and powdered, and the powder is then dusted from the skin.

Reduction of the fracture.—All the time the Thomas is being applied, the patient's foot is held in traction by an assistant who has no other duty. Often continued traction will be all that is necessary to achieve reduction when the patient is fully anæsthetised. Sometimes the upper fragment tends to ride forwards over the lower fragment and manipulation by the surgeon to correct this is often necessary. The surgeon can correct this displacement by flexing the site of fracture, usually not more than about 40°. In a transverse fracture the ends can commonly be locked and the fragments then aligned, while in an oblique fracture the pads which hold the upper end of the lower fragment well forwards must be relied on to maintain reduction. When the patient is fully anæsthetised the ring of the Thomas is slipped over the foot held by the assistant and passed to the top of the thigh. The distal end of the Thomas is then allowed to lie on the table and the limb is raised about 9 in. from the table while the traction tapes are applied.

Traction tapes.—I have found 'Elastoplast' extension plaster to be most useful for traction tapes. This plaster is not extensible in both directions: *longitudinally* it is quite rigid, but transversely it is capable of stretching and it may thus be applied easily to the varying curvature of the knee and thigh. At its upper end it should reach to about 2 in. above the fracture. The lower end is stitched carefully to a piece of strong non-extensible tape about ¾ in. wide and 18 in. long. In applying traction to the limb a start should be made at the distal end and the point of junction between the tape and extension strapping should be about 1 in. *proximal* to the malleoli. To prevent the tape from abrading the skin of the malleoli a layer of thin wool is wrapped round the ankle. The elastoplast extensions are applied one on each side of the limb, the outer one being ¼–½ in. more posterior than the inner one, so that when the traction *is finally* fixed there is a continual slight drag tending to keep the limb from falling into a position of external rotation because of the weight of the foot. The elastoplast extensions should not overlap at any part. There must be behind and in front a portion of skin never less than 1 in. wide to which there no traction strapping is attached. Failure to allow for this may lead to the development of a troublesome œdema around the ankle. When the traction strapping has been applied it is lightly bandaged by using a 3 in. cotton bandage. There must be no circular bands of strapping "to prevent the extensions slipping"; they cause œdema. Provided this method of traction is used only to maintain reduction and not to achieve reduction it is seldom necessary during the

Medical Honours

The following honours have lately been awarded to medical men

CBE —Brigadier (actg) G F Allison, MC, LRCPI, late RAMC, and Brigadier (temp) Joseph Walker, MC, MB EDIN , late RAMC

OBE —Brigadier (actg) R R G Atkins, MC, MD DUBL , RAMC , Colonel (temp) J S K Boyd MB GLASG , RAMC , Major (temp Lieut Colonel) Kingsley Fletcher-Barrett, FRCS, RAMC , Colonel (temp) H V Leigh, MD DURH , RAMC , Colonel (temp) G S McConkey, MD DUBL , RAMC , Temp Surgeon Lieut Commander H G Rees, MRCS, RNVR , and Colonel (temp) R F Walker, MC, MB BELF , RAMC

MBE —Captain (temp Major) P B Ascroft, FRCS, RAMC , Captain (temp Major) W R Day, RAMC , Temp Surgeon Lieutenant P W Isaac, MB CAMB , RNVR , Captain (temp Major) W A Oliver, MRCP, RAMC , Captain (temp Major) L S Rogers, FRCS, RAMC , Captain (temp Major) H B Stallard, FRCS, RAMC , and Temp Surgeon Lieutenant C H F Wood, MB CAMB , RNVR

DSC —Surgeon Commander Lionel Lockwood, MVO, MD MELB , RAN

Prisoners of War

The following RAMC officers have been posted as prisoners of war

WS/Captain H L Cleft, MB EDIN , WS/Captain W K Frewen, MRCS , Major D A Macpherson, MB EDIN and WS/Captain A P Russell, MB EDIN

Epsom College

The council of Epsom College will in December award a France pension of £30 p a to a necessitous medical man, fully 55 years of age, who has been registered for 5 years, and who is in need of help Forms of application may be had from the secretary's office, Epsom College, Surrey, and must be completed and returned by Oct 19

Harben Lectures

Prof J C Drummond, DSc, scientific adviser to the Ministry of Food, will deliver the Harben lectures for 1942 at the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W 1, on Monday, Oct 26, Tuesday, Oct 27 and Wednesday, Oct 28 at 3 PM His subject will be problems of war-time nutrition

Chadwick Public Lectures

On Tuesday, Oct 6, at 2 30 PM the first lecture in the autumn programme of the 30th annual series of these lectures is to be given at 26, Portland Place, London, W1, when Sir Leonard Hill, MB, FRS, will speak on The inter relation of clothing and shortage of fuel in matters of health

Before the lecture, at 2 15 PM, Sir William Collins, chairman of the trustees, will present the Chadwick medal and prize to Mr Wilfred Glyndon May, of University College, London

Royal Sanitary Institute

A meeting of the institute will be held at Oldham on Saturday, Sept 26, at 10 15 A M, when Dr E R Peirce, senior assistant port medical officer for Liverpool, will read a paper on the control of sea and air borne disease

Studentship in Experimental Psychology

The Medical Research Council invite applications from medically qualified women for a studentship for training in methods of experimental psychology, preference will be given to candidates who have had some special training in physiology or neurology, or who have already had some experience in the use of research methods The studentship will be tenable for six months during which the holder will receive training under the direction of Prof F C Bartlett, FRS, at Cambridge Payment will be at the rate of £350 per annum and the student will be expected to give her whole time to the work The award will be made with a view to possible opportunities for research into problems arising during the war, either in the services or in industry, but no definite promise of employment after the expiry of the studentship can be given Applications should be lodged with the secretary of the council, c/o London School of Hygiene, Keppel Street, London, W C 1, by Oct 5

The 114th annual meeting of the Medical Charitable Society for the West Riding was held at Leeds under the presidency of Dr T Wardrop Griffith on July 23 Since 1828 the society has distributed over £111,000 This year 12 grants, amounting in all to £1868, were made

Infectious Disease in England and Wales

WEEK ENDED SEPT 5

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 1472 , whooping-cough, 1197 , diphtheria, 787, paratyphoid, 13 , typhoid, 7 , measles (excluding rubella), 3024 , pneumonia (primary or influenzal), 379, puerperal pyrexia, 198 , cerebrospinal fever, 73 , polio-myelitis, 24 , polio-encephalitis, 4 , dysentery, 112, ophthalmia neonatorum, 94 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there were no deaths from enteric fever, 1 (0) from scarlet fever, 3 (0) from measles, 11 (1) from whooping-cough, 14 (0) from diphtheria, 52 (6) from diarrhœa and enteritis under two years, and 3 (1) from influenza The figures in parentheses are those for London itself

The number of stillbirths notified during the week was 200 (corresponding to a rate of 32 per thousand total births), including 23 in London

---

Messrs BRITISH DRUG HOUSES are prepared to supply S methylisothiourea sulphate free of charge to any clinician who wants to make a trial of this compound on the lines suggested by Smirk and McGeorge in their paper of Sept 12 It is available for this purpose in ampoules containing 2 ml of a 10% solution for intravenous injection

---

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Appointments

Colonial Service —The following appointments are announced

ALLEN, R A , MB LPOOL MO, Gold Coast
FORSHAW, H W , MB LPOOL MO, Nigeria
GILLESPIE, J E , MD DUBL , MRCPI, DPM MO, Trinidad
MOTT, G A , MB CAMB MO, Gold Coast
NICHOLSON, J A B , MB LPOOL MO, Nigeria
REED, H N , MB MO, Tanganyika Territory
SAMUEL, G N , MB MO, Sierra Leone
ROBERTS, M A W , MB DUBL , FRCS Surgical Specialist, Nyasaland

Births, Marriages and Deaths

BIRTHS

BURNS —On Sept 2, Dr Angela Burns (*née* Ricardo), wife of Dr Benedict De Lisle Burns, of Oxford—a son

FRASER —On Sept 6, the wife of Mr Donald Fraser, FRCS—a daughter

HEATON —On Sept 11 in London, Dr Winifred M Heaton (*née* Farmar) wife of Major Richard Heaton, Duke of Lancaster's Own Yeomanry—a son

LLOYD —On Sept 9, at Cheltenham, Glos, the wife of Major J P F Lloyd, RAMC—a daughter

MCINTOSH —On Sept 6, at Inverness, the wife of Captain D G McIntosh RAMC—a daughter

MILNE —On Sept 6, the wife of Dr K J G Milne, of Sheffield—a son

NAISH —On Sept 7, in Edinburgh, Dr Nora Naish wife of Surgeon Lieutenant J M Naish, RNVR—a daughter

TEARE —On Sept 8, in London, the wife of Dr Donald Teare—a son

MARRIAGES

BENNETT—ALLCHIN —On Sept 5, at West Acton, H W D Bennett to Margaret Betty Allchin, MRCS

DAVIES—EMMETT —On Sept 5, at Kirk Ella East Yorks Donald Henry Davies, BM, surgeon lieutenant RNVR, to Mavis Eileen Emmett, WRNS

DUGGAN—MACKINTOSH —On Sept 9 at Oban George Franc Duggan, FRCSE of Shotley Bridge, co Durham, to Helen Kilgour Mackintosh

DEATHS

BROWN —On Sept 12, Thomas Henry Brown, MB CAMB, of Streatham

COMPTON —On Sept 9 in London, Alwyne Theodore Compton, FRCS of Seaton, Devon

HOPKINS —On Sept 10, at Mickleover Derby Edwin Lancelot Hopkins, MC MRCS, DPH , DPM aged 53 years

O CONNELL —On Sept 4, Arthur Patrick O Connell, LRCPI , of Leed

RYAN —On Aug 28 at Port of Spain Trinidad B W I William Astle Ryan, MB DUBL, surgeon lieut commander RN (ret)

When pain on straining the site of fracture has almost disappeared the test of weight-bearing may be begun, at first under careful clinical supervision day by day Usually weight-bearing is possible with safety at about the 20th–24th week Not until the danger of angulation at the site of fracture is past should there be any passive movements at the knee-joint, in general, where passive movements are used at all they should be carried out under anæsthesia and by the surgeon in charge of the case—that is, they should take the form of a manipulative breakdown of knee adhesions Anæsthesia for the manipulation should be full In most cases simple gas anæsthesia does not produce an adequate relaxation of the thigh muscles This passive manipulation of the knee is required in about 30% of cases in order to develop knee flexion to fully 90° Once the knee flexion has been developed to this extent the development of further movement is influenced almost entirely by the man's own efforts, and seems to depend more particularly on the nature of his work For instance, a collier, before he can do his work properly, requires to have a knee in which there is almost normal flexion, but in many forms of occupation the man expresses himself as completely satisfied with knee flexion when it has reached about 110°, and finds that the disability does not constitute an incapacity for work In general, this stage of recovery is expected to be reached after about 32–36 weeks, and a case in which this degree of recovery is not achieved by the end of a year is regarded as slow

X rays in this method of treatment are used merely to check the position of the fracture Maintenance of length may be determined quite satisfactorily by measurement taken between the anterior superior iliac spine and the internal malleolus Angulation can be corrected by the insertion of wool pads or alteration in the size of the wool pads inserted between the limb and one or more of the splints Little regard is paid to X-ray shadows in determining the time for weight-bearing, which is assessed on purely clinical grounds

Complications—Loss of length of more than ¾ in indicates a failure in technique—a lessening of the traction and immobilisation at some time after the reduction of the fracture and during the first six weeks If length has been maintained during that time, shortening hardly ever occurs In general, one expects the amount of shortening to be less than ½ in, lengthening up to ½ in may be produced by too enthusiastic tightening of the traction tapes in children

Angulation at the site of fracture may be due either to failure to correct angulation by means of wool pads or to an improperly fitting calliper which has allowed the limb to bear weight too early I have not seen a case of non-union with this method The prevention of pressure sores does not require any special skill, provided the nurse is willing to carry out the necessary regular attention to the skin Incontinence does not necessarily imply the certain development of pressure sores where adequate nursing care is given

SUMMARY

In the treatment of a fracture of the shaft of the femur early and adequate recovery of knee movement is more important than loss of length up to ¾ in

In using a Thomas splint with fixed skin traction, the most important points in technique are as follows. the fracture is reduced under full anæsthesia and the skin traction is used only to maintain reduction, traction is maintained with the knee-joint kept in 10° of flexion by means of wool pads and a back splint, counter-traction is upon the ischial tuberosity

The use of the Balkan beam greatly facilitates nursing care, and helps to maintain general muscular function of all the limbs and the comfort of the patient.

BRONCHOGRAPHY IN CHILDREN

C ELAINE FIELD, MD LOND, MRCP
FIRST ASSISTANT TO THE CHILDREN'S DEPARTMENT AT
UNIVERSITY COLLEGE HOSPITAL, LONDON

SINCE the introduction of iodised oil as a method of investigating the bronchial tree by Sicard and Forestier (1922) many different techniques have been described In the adult satisfactory bronchograms are obtained by the endotracheal method described by Forestier and Leroux (1923) using local anæsthesia for the skin and cocaine in the trachea. This method was first applied to children by Armand-Delille (1924) but most children have a dread of the needle, and lack of cooperation with crying and coughing causes iodised oil to enter the alveoli of the lung or be coughed up and swallowed, with unsatisfactory bronchographic results This may be overcome by the original supraglottic method in which the patient puts out his tongue and the iodised oil is dripped over the back of it (Sicard and Forestier 1922 and 1932) or by the nasal method (Forestier and Leroux 1935), in which the tongue is pulled forward and the oil is dripped through the nose In both these techniques local anæsthesia must be used, children are rather sensitive to cocaine and its equivalents in any quantity, and unless cooperation is really good the oil passes down the œsophagus rather than into the trachea Bronchography under general anæsthesia is more suitable for children but so far I have failed to find an anæsthetic that is thoroughly satisfactory. Chloroform gives the best pictures but is too dangerous, especially since the child must be sat up during the procedure Nitrous oxide causes increased respiratory excursions with the result that the iodised oil enters the alveoli of the lung and obscures the picture Open ether is the anæsthetic of choice but has the disadvantage of causing excessive secretion in the bronchi, especially in areas of bronchiectasis, which may prevent the oil from entering that part of the bronchial tree about which information is specially desired This disadvantage can be overcome to a certain extent by giving adequate doses of atropine beforehand Jacoby and Keats (1938) advocate ether anæsthesia and the supraglottic method and Barsby and Bonham-Carter (1941) recommend ether with the nasal method Basal narcotics and hexobarbitone have the disadvantage that they fail to abolish the cough reflex

To overcome these difficulties a technique has been devised which abolishes consciousness of the prick of the intratracheal needle but leaves the child fully conscious during the introduction of the iodised oil Excellent bronchograms can thus be obtained, and subsequent bronchograms are easier to take because the child, having suffered no pain, is not apprehensive

TECHNIQUE

The child undergoes preparatory tipping and breathing exercises until the moist sounds in the chest are greatly reduced and the quantity of sputum diminished On the day of examination, breakfast is omitted and twenty minutes before the operation min 5–10 of 'Nepenthe' (Ferris) are given Tipping is continued until the patient is sent for, and on arrival in the X-ray room the procedure is explained to the child and a rehearsal of the positions required is carried out (these will be described later) To give the child no time to develop fears a quick gas and oxygen anæsthesia is administered and the special needle (fig 1) is introduced through the cricothyroid membrane As soon as the operator is certain, on withdrawing the stilette, that the needle is in the trachea, the child is allowed to come out of the anæsthetic A hissing noise during respiration, or the withdrawal of air into a syringe are signs that the needle is in the trachea As consciousness is being regained, min 5–10 (according to the age of the child) of 2% butethanol ('Decicain') is injected through the intratracheal needle, the patient usually coughs and sprays the solution over the bronchi The iodised oil is injected when the patient has fully recovered from the anæsthetic During the next procedure the child, while encouraged not to cough, is kept well tilted to the side that is to be filled until the X rays have been taken

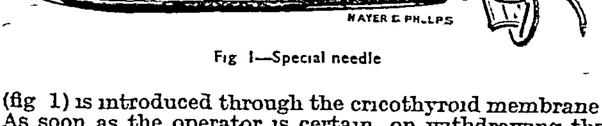

Fig 1—Special needle

course of treatment to change the traction strapping because of slipping

Back splints and side splints —The use of a back splint is essential It should reach almost up to the fold of the buttock and down to a point about 1–2 in proximal to the internal malleolus Its ends must be well padded , I use thin adhesive felt over each end and on top of that a layer of cotton-wool Two side splints for the thigh are an advantage but not always essential The inner one should be short enough to reach down almost to the internal condyle of the femur without its upper end bearing against the ring of the Thomas The outer splint should reach from just below the great trochanter to a point above the external condyle of the femur Their ends should also be well padded At the site of fracture a large wool pad between the back splint and the limb maintains the important normal anterior bowing of the shaft of the femur Where there has been some difficulty in correcting anterior displacement of the upper fragment this pad may appropriately be disposed just distal to rather than precisely at the site of fracture, thus holding forward the upper end of the distal fragment A second woollen pad, placed behind the knee-joint, is of such a size that when the splints are strapped in position the knee-joint is immobilised in about 10° of flexion this is most important Observation has shown that where the limb is immobilised with the knee in full extension there is always great difficulty in restoring knee movements Where the knee is immobilised in a little less than full extension the development of knee movements is subsequently comparatively easy I believe this is because the last few degrees of extension of the knee-joint are associated with internal rotation of the femur on the tibia By using a pad of wool to immobilise the knee in 10° of flexion this locking of the knee-joint is avoided, and when the patient subsequently begins to develop knee flexion he can apply the full flexing power of the hamstrings

When the straight splints are ready for application, and while the assistant is still maintaining traction on the foot raised about 9 in above the splint which is lying on the table, the surgeon carries out the manœuvres necessary for complete reduction of the fracture and the splints and pads are then applied The splints are held in position by 2 in wide adhesive strapping encircling the limb at four levels The two pieces of strapping above the knee should be disposed so as to avoid causing any displacement of the fracture , their positions vary according to the level of the fracture The error to be avoided is that of putting tight strapping just below the fracture and so producing backward displacement of the upper end of the lower fragment The other two pieces of strapping are placed one at the level of the tibial tuberosity and the other near the distal end of the back splint The strapping should not, at any part, be adherent to the skin , a thin layer of cotton-wool is placed under the circular bands to prevent them adhering to the skin The limb is therefore in a tunnel of splints which do not impede traction

The splinted limb is now lowered upon the Thomas, and is supported in the splint by three double layers of flannel, 6 in wide, fastened by paper clips or safety pins at the outer side The sag of the slings should be arranged so that about two-thirds of the diameter of the limb is anterior to the plane of the Thomas splint While the assistant continues to maintain traction on the foot, the tapes are passed round the sides of the Thomas and fastened over the notch at the distal end The limb may now be bandaged together with the Thomas, by a flannel bandage reaching from the ankle to the upper part of the thigh There is no need to use any appliance for preventing foot-drop The foot is kept from dropping by the often repeated muscular efforts of the patient Foot-drop should not develop unless the injury is complicated by a nerve palsy, in which case some appliance is necessary

The Balkan beam greatly increases the mobility of the patient in bed, so that he may sit up or lie down at his own convenience It provides a means of exercising not only the injured limb but all the limbs, and is of great assistance in keeping the ring of the Thomas in its proper position in relation to the ischial tuberosity Nursing care is greatly simplified by its use In Walton Hospital, for the sake of uniformity, a fractured femur is always treated in a Nesbit-Evans bedstead using the Nesbit Evans bed crane, the vertical limb of which is used as a support for the horizontal beam of the Balkan frame The Thomas splint should be slung from the beam by two attachments only, one to the front of the ring of the Thomas and the other to the distal end of the Thomas The balancing weights are such that the patient can easily raise and lower the limb If a patient must be urgently transferred to another hospital—which happens oftener under war conditions than it did in peace-time—the fixed-traction method permits of transport without loss of position of fragments It is only necessary to cut the attachments of the Thomas to the Balkan beam

Nursing care —Pressure points which require to be treated regularly are at the upper and lower ends of the back splint , in the neighbourhood of the ankle and heel, and on the skin around the upper part of the thigh adjacent to the ring During the first two or three weeks the skin over the ischial tuberosity just below the anterior superior iliac spine must receive attention every four hours, night and day The task does not require any special skill, but it must not be neglected The skin is cleaned, dried, dusted and pulled by the fingers so that every few hours a different area of skin takes the pressure of the ring Approach to the skin over the ischial tuberosity is easy if the uninjured limb is well abducted while the injured limb is raised If the skin over the ischial tuberosity is allowed to get so sore that the pressure of the ring is too painful for the patient to bear, the method has failed and the surgeon must adopt some form of weight traction which does not, in my experience, give so high a general level of results It is the nurse's duty often during the day to instruct the patient to dorsiflex the ankle For the first few weeks the traction tapes should be tightened if necessary every eight hours, so as to keep a continuous drag on the limb Usually after the sixth week the amount of traction can be decreased and it is merely necessary to keep the traction tapes taut

Maintenance of function , weight-bearing —The patient is encouraged to contract the thigh, calf and anterior tibial muscles throughout the whole treatment Use of the Balkan beam and bed crane makes it easy to encourage the use of the muscles, and from the day after the application of the splint the patient should be able to sit up to take meals

In general, the limb must be kept in the Thomas for about ten weeks, when the patient may begin to walk in a calliper The actual change from the Thomas splint to the calliper is made when the fracture has united sufficiently to sustain the weight of the limb, but not soundly enough to bear the weight of the body Tenderness and pain on straining the site of fracture should be slight , a good rough test is to observe the patient's ability or otherwise to lift the unsplinted limb from the bed without pain at the site of fracture

A well-fitting calliper is important, in the form of a Thomas splint with the distal ends bent and implanted in a brass tube inset in the heel of the boot The tube should be about in the middle of the heel but sloping from within outwards in a forward direction at an angle of about 15° This slight angulation of the tube prevents the toes turning inwards during walking Great care should be taken about the fitting of the ring so that there is no possibility of it slipping from the ischial tuberosity The sides of the calliper should be of such a length that the limb does not bear weight, and the space between the man's heel and the upper surface of the heel of the boot should be about ¼ in A patient describes the feeling of wearing a correctly fitting calliper "It is as if I am sitting on the ring" The boot into which the calliper is fitted should preferably be of soft leather or cloth, so that it can be worn with the calliper without discomfort in bed The patient sleeps and walks in the calliper and boot, usually for three or four weeks until union is sound enough to allow of active knee movements without pain at the site of fracture When union has reached this stage the calliper may be given up at night and for three or four periods of half an hour each during the day while the patient practises active knee movements cricothyroid membrane In all cases the neck should be extended by placing one pillow under the shoulders , too much extension flattens the trachea and makes introduction of the needle difficult The first prominent cartilage in the child is the cricoid and the needle is introduced into the V-shaped notch above this , it is a good practice to feel the child s neck while he is still in the ward and also just before the operation, so as to be thoroughly familiar with the anatomy There should be no ill effects afterwards and usually the child can have a full meal when the action of the butethanol has worn off

The aim of the operator should be to outline, not fill, the bronchial tree with iodised oil—which should reach just to the alveoli without entering them Only one lung should be filled (fig 4) so that a clear lateral picture can be obtained Usually after 3 weeks of tipping this lung has cleared sufficiently of iodised oil for the other side to be filled

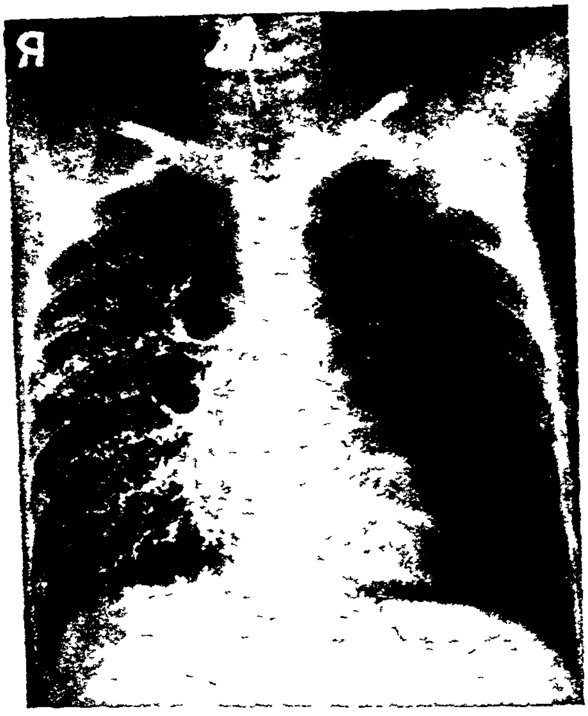

Fig 4—Anteroposterior radiogram , one side filled

SUMMARY

A new technique of bronchography in children is described in which they are anæsthetised with nitrous oxide, while a special intratracheal needle is introduced During the injection of the iodised oil no anæsthetic is administered, since the best bronchograms are obtained in the fully conscious patient

The method is suitable for children aged 5 years and over For infants under 5 the less satisfactory method with open ether anæsthesia is used

A war-time tipping board made with simple materials is described

I wish to thank Dr W J Pearson, physician to the children's department at University College Hospital, and Dr W G Wyllie at the Hospital for Sick Children, Great Ormond Street, for their help, and Dr H N Webber for his advice on anæsthetics

DIRECTOR OF PATHOLOGICAL SERVICES, MANCHESTER MUNICIPAL HOSPITALS

IT is now admitted that one of the chief disadvantages of sulphonamide therapy is the tendency for these drugs to give rise to renal complications Sulphanilamide itself, on account of the relatively high solubility of both the drug and its acetyl compound, is almost entirely free from this tendency, but hæmaturia and more severe renal damage have been noted with sulphapyridine and sulphathiazole Recent reports indicate that sulphadiazine treatment is not free from similar risks The published work on this subject, mostly American, has been reviewed by Peterson and Finland (1941) From this it appears that various degrees of hæmaturia are common with all the sulphanilamide derivatives, but in most cases there is no evidence of permanent renal damage

A few cases of sulphapyridine anuria with recovery have been reported in this country (Leedham-Green 1941, Rogan and Cruikshank 1942, Laird 1941, Spence 1941) and the clinical findings in a fatal case have been given by Fletcher (1941) The only report including autopsy findings we have seen in the English journals is that of Whitehead (1941) The case recorded here showed hæmaturia followed rapidly by anuria, confirmed at autopsy as being due to blockage of the ureters with acetylsulphapyridine

CASE-HISTORY

A man, aged 43, was admitted to hospital on May 30, 1942 Five days previously treatment with sulphapyridine had been begun for lobar pneumonia He was given an initial dose of 2 g followed by 1 g every four hours, receiving in all 22 g On the day before admission the urine was scanty and blood-stained and sulphapyridine was discontinued He then complained of pain over the bladder and no further urine was passed Severe pain in the hypogastrium and the tip of the penis were present on admission He was quite rational at the time of examination but was reported to have been delirious occasionally The skin and mucous membranes were pale, the tongue dry and furred Temperature 98° F , pulse rate 88 and respirations 28 per min , blood-pressure 130/80 mm Hg Slight retraction of the abdomen, which was tender over the whole of the lower half , no loin tenderness , *no œdema* , fundi normal A catheter was passed quite easily but no urine was obtained on this or two subsequent occasions Fluids were taken freely by mouth and he received 3000 c cm. by intravenous drip, partly 5% glucose saline and partly 4 28% sodium sulphate On the next day the pain was less severe but the abdomen became more distended and he vomited 10 oz of fluid Although he was rather drowsy consciousness was maintained until shortly before death, 40 hours after admission to hospital, no urine having been passed for 60 hours Twitching of the extremities was not noted at any time The blood urea 3 hours before death was 100 mg per 100 c cm

At *autopsy*, 24 hours after death, findings were as follows Heart (284 g) a few petechial subendocardial hæmorrhages in the left ventricle Lungs about 200 c cm of slightly bloodstained fluid in each pleural sac , both lungs congested and lower lobes œdematous Liver (1247 g) smaller than normal , surface of coarse morocco leather type cut surface confirmed the appearance of multilobular cirrhosis Spleen (227 g) enlarged, firm, chronically congested Urinary tract kidneys showed similar appearances ; the general anatomy was not disturbed, there was no naked-eye evidence of acute nephritis, and stripping the capsule left a smooth normal-looking surface , on each side the pelvis and ureter were greatly dilated (right 0 75 cm , left 1 cm in diameter) and completely packed with blood-clot mixed with lighter, whitish particles , at the lower end of the ureters were some elongated masses which appeared to be almost entirely crystalline, and it was with difficulty that this material could be " milked " from the ureters into the bladder The epithelial lining of pelves and ureters showed many blotchy hæmorrhages and there was hæmorrhagic staining of the surrounding connective tissues The bladder contained a few c cm of

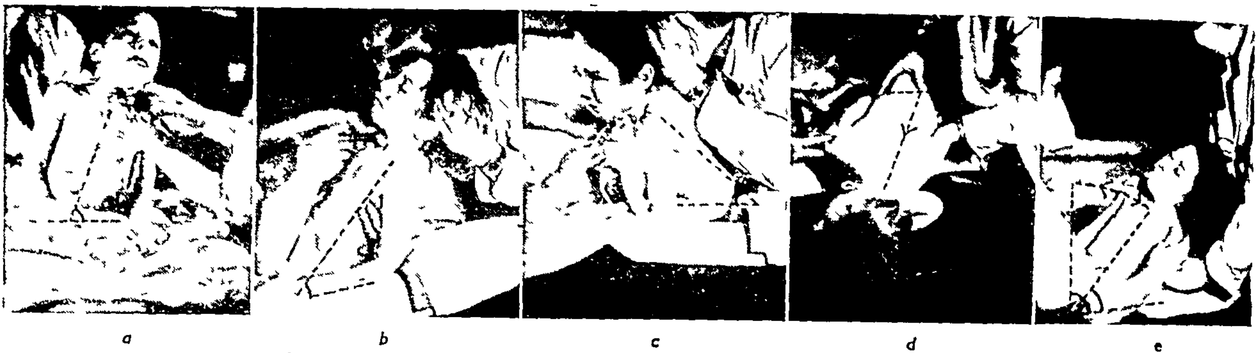

Fig 2—(a) Child kept well tilted to the left during whole procedure until X-ray photographs have been taken (To fill left side only)

(b) Iodised oil, 2 c cm is slowly injected with child leaning backward at 45°, pause of 1 min after injection (To fill dorsal and lower lobe branches)

(c) Iodised oil, 2 c cm , is slowly injected with child leaning forward at 45°, pause of 45 sec after injection (To fill anterior branches and middle lobe)

(d) Iodised oil, 1 c cm , is rapidly injected with child in the sitting position child is then immediately inverted over left side of the operating table fo 30 sec (To fill the upper lobe)

(e) A further 2 c cm of iodised oil is injected with child in sitting position child is then slowly tilted backward through 45° and forward to the sitting position several times (To ensure complete filling of lower lobe, usually the most difficult to fill)

Fig 2 shows the positions required during the introduction of iodised oil, to ensure complete filling of all parts of the left lung

It is important, after getting the child to adopt each new position, to withdraw air into the syringe before injecting the oil, so as to be certain that the needle is still in the trachea , otherwise oil may be injected into the surrounding tissues The quantities given (fig 2) are suitable for a child of 7 , for a younger child slightly less oil would be used and for an older child a little more, the dose in either case being kept preferably between 5–10 c cm The child is then laid down on the side that has been filled and X-ray photographs are taken If by this time he has not coughed, he is instructed to give a gentle cough , this helps to give an even spread of the oil Lateral and anteroposterior X-ray plates are exposed, and then a second lateral, to ensure that a good lateral picture is obtained Even if the child coughs the pictures are often good If the radiograms show incomplete filling in any area, more iodised oil can be introduced with the child in the appropriate position

The method requires a certain amount of cooperation from the child , it is practical for those of five years and over, and even for children under five who happen to be good patients

For uncooperative children the less satisfactory method with open ether anæsthesia must be tried The same technique can be used except that butethanol is not necessary and atropine, gr 1/100, must be given half an hour beforehand All procedures are carried out outside the X-ray room, the child being brought in for radiography only, ether and mask being left behind to eliminate the risk of an explosion Anæsthesia is continued until the radiograms have been seen, when if parts are unfilled more iodised oil can be injected It is important that the child should at no time be allowed to cough, because the oil enters the alveoli of the lung irregularly when the patient is under a general anæsthetic The anæsthetic should be given by some one accustomed to the technique Oxygen can be used with advantage to combat cyanosis but nitrous oxide should never be used when introducing iodised oil because it tends to make the oil enter the alveoli

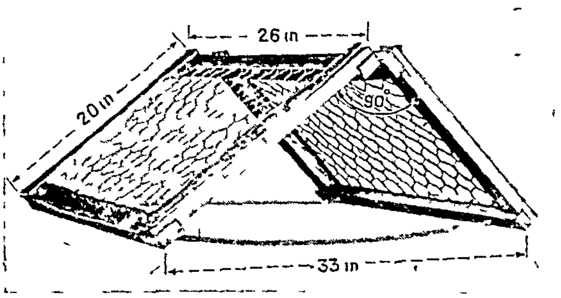

Fig 3—War time tipping board made from common materials

EQUIPMENT

Iodised oil —'Lipiodol' (Bengué) 40% is recommended but other products such as 'Neo Hydriol' (M&B) may be used, unfortunately they have an odour which the child dislikes There is no necessity to heat the iodised oil providing it has been at room temperature for a short time

The needle (fig 1) is a modification of Delille's trocar and cannula It consists of a stilette attached to a handle which fits into a curve needle, the bevel of which is arranged like a lumbar puncture needle so that it separates the fibres of the cricothyroid membrane and does not cut across them At the hilt of the needle there is a metal plate with two perforations so that by means of tape it can be held in position like a tracheotomy tube Two small handles on the upper and lower surfaces of the plate enable the surgeon to take a good grip of the needle The stilette is prevented from rotating in the needle by a notch on the upper surface An ordinary 10 c cm Record syringe is quite satisfactory for use with this needle, but it must fit well into the needle because withdrawal of air is used as the indication that the needle is in the trachea, should there be a leak a false impression is gained and oil may be injected into the surrounding tissues The needle should be sharp and the forefinger should be placed on the top of it when introducing it into the trachea because the instrument is delicate and might break at the hilt

The tipping board (fig 3) shows a war time board using the minimum of wood , it can be folded and carried about easily, even by the child himself Two square frames of wood are hinged together on one side and the opposite sides are connected by two pieces of rope The angle at the top is 90°, and the length of the base 33 in , the boards are each 26 in by 20 in Strips of canvas or wire netting fill the intervening spaces

COMPLICATIONS AND DIFFICULTIES

Surgical emphysema is rare if the puncture hole is rubbed vigorously immediately after withdrawal of the needle, to encourage closure of the needle track , it occurred once only in 100 cases Sepsis around the puncture hole is seldom seen if aseptic technique is practised , it also occurred once in the 100 cases It is important to make sure that bronchiectatic areas are almost empty of secretion before bronchograms are taken, otherwise filling with oil is inadequate, or septic secretion trickles into neighbouring portions of lung and causes pneumonia In this series pneumonia developed in one advanced case of bronchiectasis where the cavities could not be sufficiently emptied The danger of injecting iodised oil into the surrounding tissues rather than the trachea is exaggerated , it should never happen if the syringe fits closely into the needle, and if air is withdrawn into the syringe from the trachea after each new position has been taken up and before the oil is injected Occasionally the needle catches on the back of the trachea , to correct this, the syringe and the base of the needle must be raised, so that the point of the needle is brought forward Sometimes there is difficulty in distinguishing the

BP 165/95 mm Hg On passing a catheter 1 oz of almost pure blood was obtained Morphine gr ¼ and atropine, gr 1/75 were administered and the dose repeated after an hour owing to persistent pain and restlessness Intravenous infusion with 2½% sodium citrate was commenced immediately, temporary suspension was necessary after 2 hours because of a moderately severe rigor He was encouraged to take as much fluid by mouth as possible but even small amounts of sweetened cordial were returned Twenty four hours after the original onset of urinary symptoms, the pain in the loins had diminished and the left loin was only moderately tender The blood-urea was 36 mg per 100 c cm and the blood pressure had fallen to 120/80 mm Hg At the end of 36 hours—30 hours after the beginning of treatment—he had still passed no urine in spite of intravenous infusion with 12½% glucose, hot poultices to the loins, and repeated warm colonic irrigations The total fluid intake by this time was 5 pints, of which only ½ pint had been taken by mouth, 22 g of sodium citrate had been administered intravenously The pulse was satisfactory and he no longer complained of pain, though there was still aching in the loins The complexion had assumed a muddy tint, some moist crepitations were now audible at the bases of both lungs, and his general condition was considered to be deteriorating Operation was decided on

At 10 P M on July 17 cystoscopy was performed The bladder contained ½ oz of very dark amber coloured urine The trigone was much congested with areas of submucous hæmorrhage and small scattered deposits of crystalline yellowish brown and silvery debris Both ureteric orifices were very œdematous, the right being extremely difficult to locate owing to locally adherent debris and clot No flow was visible from either orifice A No 6 Nyland catheter was inserted into the left ureter with some difficulty owing to local distortion, and passed reluctantly, with a grating sensation for the first 5 cm After the initial resistance had been overcome, the catheter passed easily and without hindrance to the renal pelvis and dark amber coloured urine escaped at a rapid drip The right ureteric orifice was completely blocked by a small, hard, protruding concretion which was dislodged with difficulty The catheter met no further obstruction in the right ureter, from which urine of similar characteristics to that of the left escaped The urine from both catheters which were left in place, was acid

Further analysis of the urine from the bladder revealed many red cells and sulphapyridine crystals The crystals have a characteristic appearance, being slender and sharp pointed and clustered together in bundles like sheaves of wheat No crystals were found in the ureteric specimens, both of which contained many red cells and debris The sulphapyridine content of each was left 192 mg, right, 217 5 mg per 100 c cm

The patient's general condition rapidly improved after the operation and the output from each ureter for the next 12 hours was 23 oz of heavily blood stained urine Vomiting had ceased, so that fluids were given by mouth, the intake for the first 24 hours being 8½ pints, and output 7 pints Temporary blockage of one or other catheter was relieved by irrigation with sterile saline and both were finally removed after 60 hours Macroscopic hæmaturia ceased after 48 hours and microscopic after 96 hours Intake and output thereafter remained entirely satisfactory

Further cystoscopy six days later (July 23) showed great improvement in the appearance of the trigone, though both orifices were still surrounded by œdema and submucous hæmorrhage Catheterisation was easy and revealed no obstruction Dye excretion from both kidneys was normal Examination of the urine on Aug 1 showed sp gr 1014, acid reaction, a faint haze of albumin and microscopically a few pus cells, the blood urea and renal function tests were normal

DISCUSSION

This case presents many of the features noted in those previously published, but he came under our care too late in the illness to allow us to observe events immediately preceding anuria Seligman (1941) has reported a case of anuria following only 8 g of sulphathiazole during which vomiting was excessive He pointed out that excessive vomiting may play an important part in causing concentration of the drug in the urine with subsequent ureteric obstruction from acetyl sulphathiazole crystals It is noteworthy that vomiting was not a complication of sulphapyridine therapy in our case Thompson and others (1941), in a report of a case of anuria following sulphadiazine therapy, doubted the significance of an alkaline urine in preventing crystalluria, for the reaction of the urine in his particular case proved to be alkaline in every specimen save one Thus, the use of alkali, even when given early, is not proof against acetylisation In any event, the administration of alkali in an established case of urinary suppression could hardly be expected to affect the reaction of the urine, since the kidneys are not secreting—a point borne out by observations in the present case

With regard to the prodromal signs of anuria, particular attention should be paid to the urinary output since in Thompson's case the output began to fall slowly on the third day and after 11 g of sulphadiazine, there was no gross hæmaturia However complete anuria did not develop until the eighth day, by which time 38 g had been given Nausea and vomiting were absent throughout The importance of the urinary output has also been stressed by other observers (Carrell, Shea and Pike 1940, Laird 1941, Schulte, Shidler, and Niebaner 1942) From the published work it appears that oliguria and anuria may follow the administration of even small total quantities of this group of drugs, again emphasising the importance of close observation on the urinary output throughout chemotherapy Laird emphasises also the importance of maintaining a daily fluid intake of at least 3000 c cm prophylactically as well of making frequent examinations for microscopic hæmaturia

Concerning the pathology of sulphonamide anuria, there is much evidence that mechanical obstruction takes place in the pelvis and ureter rather than in the renal parenchyma Apart from the support given to this contention by successful ureteric catheterisation in these cases, further evidence is found in the post-mortem records of a case described by Schulte and others (1942) in which death occurred 11 days after pneumonectomy, 54 g of sulphadiazine had been given and at autopsy yellowish-orange granular deposits were found in the right renal pelvis and throughout the course of the right ureter, careful histological examination of both kidneys failed to demonstrate any crystals in the renal tubules Another fatal case has been recorded by Backhouse (1939) in which post-mortem examination revealed sulphapyridine calculi causing obstruction at the lower ends of the ureters, both of which contained urine under pressure The rationale of ureteric catheterisation thus appears to be established, and is borne out by its successful employment in the reported cases Tsao as early as 1939 described a fatal case of anuria after sulphapyridine therapy, and attributes the death of the child to concretions completely blocking each ureter, he said that the assistance of a urologist might have saved life Laird (1941) also considered ureteric catheterisation a life-saving operation in his case and suggested that an arbitrary period of 12 hours anuria was sufficient indication to perform this operation in every case Rogan and Cruickshank (1942) have described a case of sulphapyridine anuria treated by 'Inductotherm' applied to the loins and advise that this method should be tried before resorting to ureteric catheterisation They agreed, however, that if the condition was due to uretero-vesical obstruction catheterisation would be required Inductotherm treatment would admittedly be valuable if obstruction could be shown to occur in the kidneys, but the site of the obstruction can only be determined by cystoscopy and catheterisation, and the use of short-wave apparatus in war-time, unless it is efficiently screened, is prohibited

In the prevention of oliguria, a large fluid intake throughout chemotherapy is of prime importance

thick, slightly bloodstained fluid and the mucosa showed several small hæmorrhages.

Microscopical examination of kidneys.—The lining of Bowman's capsule was swollen, with varying amounts of desquamation. The tufts were not swollen but showed evidence of shrinkage and disintegration. The capsular spaces contained partly amorphous eosinophilic material and partly cellular debris. There was moderate swelling and cytoplasmic granularity of the tubular epithelium, especially of the first convoluted tubules and in most of the tubules there was cellular and amorphous debris. A few of the collecting tubules contained blood and near the pelvis the intertubular vessels were greatly dilated. There was an extensive hæmorrhagic infiltration into the tissues of the pelvis. Frozen sections, examined with crossed Nicol prisms, failed to show any crystalline material in the kidney substance. There was no fatty change in the tubular epithelium. The material from the ureters consisted of blood and masses of crystals, mostly sheaves of elongated needle forms, sometimes shorter rectangular rods found either singly or in groups. The fluid from the bladder contained 47 mg. per 100 c.cm. of total sulphapyridine, only a trace being demonstrable in the free form, and 93 mg. per 100 c.cm. of urea. It contained very large numbers of epithelial cells, blood cells and other organised material. The white material from the ureters contained 78% acetylated sulphapyridine, no free sulphapyridine being detected.

DISCUSSION

The sequence appears to have been the precipitation of acetylsulphapyridine within the kidney, followed by a massive deposition in the pelvis and ureter leading to hæmorrhagic pyelitis and ureteritis, but there was also evidence of glomerular and tubular damage. It is difficult to say whether the latter changes were due to the direct action of the sulphapyridine or were wholly or in part a secondary effect of the obstruction; but we have observed similar glomerular and tubular changes in the kidneys of rats fed on large doses of sulphapyridine over a period of four weeks and not showing ureteral obstruction. Peterson and Finland give instances of similar lesions and it is significant that Antopol (1940) describes similar changes in the kidneys of a man who died after showing only microscopic evidence of hæmaturia. Whitehead (1941) found crystals in many sections of the kidneys but no sulphapyridine concretions in the ureters. He suggested that the ureters were blocked at their lower ends by subepithelial hæmorrhages.

The solubility of acetylsulphapyridine is about half that of sulphapyridine—34·1 mg. as compared with 61·3 mg. per 100 c.cm. at pH 6·5 (Macartney et al. 1942)—and it seems probable that in patients who develop renal complications there is an idiosyncrasy causing an abnormally high percentage of the drug to be excreted in the acetylated form. It is not possible to prove this point in this particular case since estimations of the free and acetylated sulphapyridine in blood and urine before the onset of anuria were not made. As in the other reported cases the total amount of sulphapyridine given does not appear to have been the determining factor. This patient received 22 g. over four days; Rogan and Cruikshank's case had 15 g. in two days; Leedham-Green's 12 g. in three days; and Whitehead's 17 g. in forty hours.

Several writers (Leedham-Green 1941, Backhouse 1939) emphasise that treatment with large amounts of fluid and with alkali may be effective. In our case it is noteworthy that the patient had been having an alkaline mixture on account of gastric symptoms for twenty-four hours before receiving sulphapyridine, and he continued to take alkalis throughout the illness. In any event it seems very doubtful whether the urine can ever be made sufficiently alkaline to increase the solubility of acetylsulphapyridine materially. This patient was reported to have taken fluids freely at home, and during two days in hospital he took at least 4½ pints by mouth and 3000 c.cm. by intravenous drip. Ureteric lavage was not attempted and it is impossible to state what the result of this would have been if carried out at an early stage. Judging from the condition at autopsy, where pelvis and ureter were found to be packed with clot and crystals throughout their course, it is difficult to imagine that the procedure could have been successful in the later stages of the illness.

SUMMARY

The clinical and post-mortem findings are recorded in a case of sulphapyridine blockage of the ureters after a total dosage of 22 g. The lesion was essentially a hæmorrhagic pyelitis and ureteritis, following massive deposition of acetylsulphapyridine.

SULPHAPYRIDINE ANURIA
TREATED BY CYSTOSCOPY AND URETERIC CATHETERISATION

R. C. S. BENSON, M.B. LOND.
R. C. PERCIVAL, F.R.C.S., M.R.C.O.G.
TEMPORARY SURGEON LIEUTENANTS R.N.V.R. AT A ROYAL NAVAL AUXILIARY HOSPITAL

ANURIA during the administration of one of the sulphonamide drugs is an uncommon but serious complication. Finland and his associates (1941), in reporting a series of 446 cases of sulphadiazine therapy, noted that gross hæmaturia and anuria occurred in 1 case only. A number of cases have been reported chiefly from America, in which ureteric catheterisation was successfully employed. Laird (1941) however, in a paper concerning 794 cases of gonorrhœa treated with sulphapyridine, reported gross hæmaturia in only 5 cases and anuria in 1, the latter responding to catheterisation of one ureter. While but few fatal cases have been recorded, it is considered that, in view of the wide use of sulphonamides, further attention should be drawn to this serious complication and its prevention, and to a safe and successful method of treatment. In the following case, anuria complicating the sulphapyridine treatment of pneumonia was successfully treated by ureteric catheterisation.

CASE-RECORD

A well-built chief petty officer, aged 38, began his illness at sea nine days before admission with general malaise, cough and pain in the right chest. Three days later, when he reported sick, bronchopneumonia was diagnosed and sulphapyridine therapy begun, a total of 21 g. being given during the next three days. It was discontinued on the fourth day of treatment, by which time he was apyrexial and the chest condition progressing satisfactorily. No vomiting had taken place. Thirty six hours after the cessation of sulphapyridine, he suddenly experienced burning pain in the penis and passed a small quantity of blood stained urine. There was no history of any earlier dysuria or hæmaturia, but no record of fluid intake or output had been kept for the preceding twenty four hours. However, a few hours previously, he was stated to have passed a usual amount of apparently normal urine. On admission to this hospital six hours later, on July 16, 1942, he complained of a constant, severe, aching pain in both loins and had persistent urgency but could void no urine. The only other complaints were of nausea and flatulence, and he had vomited shortly before admission.

His previous history included an illness presenting the features of acute nephritis at the age of 15 years. Since then there had been no symptoms suggestive of permanent renal damage.

He was suffering fairly severe pain. His temperature was 97·6° F., pulse rate 68 and respiration 28 per min. His complexion was sallow, and tongue slightly furred. Movement of the right hemithorax was moderately impaired, with slight dullness on percussion in the right lower axilla. Many fine and medium crepitations were also heard in this area, and the signs were considered to be those of an area of consolidation undergoing resolution. The abdomen was soft but there was extreme tenderness in both loins, particularly the right. There was no tenderness on firm palpation over the bladder.

(1) Careful supervision of the population at risk, including occasional week end visitors of the evacuee families Communications were sent to the medical officers of health of the areas in London where the persons resided and they were followed up there with negative results

(2) Fullest use of laboratory facilities and close collaboration with the laboratory workers

(3) Immediate removal to hospital of all ascertained cases, including many that would not have been diagnosed at all without strict and repeated bacteriological control

(4) Preliminary instructions on July 10 to boil all water and milk, followed on July 14 by cutting off the water supply By July 18 main water supply was laid on to the houses of the court, taps being installed in the yard

(5) Relaying of all defective drainage in the properties concerned

SOURCE OF THE OUTBREAK

The only factor common to the inhabitants of the court and not shared by the rest of Brixworth was the water-supply, which for this reason alone was strongly suspected from the start Bread and milk could be dismissed as possible sources of the outbreak , blood and two samples of fæces and urine from all the staff of the bakery and dairy supplying the court were investigated, with negative results Suspicion of the water was strengthened by the very high proportion of cases among the population at risk (21 out of 34) and by the fact that no cases occurred in the rest of the population of Brixworth, a village of some 2000 inhabitants The isolation of *Bact paratyphosum B* from the water collected on July 12 completed the chain of evidence

The method by which the water became polluted can only be guessed at Several recent cases of paratyphoid B fever in the neighbourhood had to be considered Earlier in the year there had been a small outbreak in a residential school 6 miles to the east Three weeks before the outbreak in the court a sporadic case occurred in a village 2 miles to the west and almost at the same time a case was notified in a village 6 miles to the north. No connexion between any of these cases and the outbreak in the court could be traced Careful inquiries showed that five of the patients in the court had had attacks of diarrhœa in April These may have been the result of some non-specific pollution of the well but it is possible that they were mild cases of paratyphoid fever and that one or more of them had continued in the carrier state up to July Laboratory examinations in July showed that all of these five were excreting *Bact paratyphosum B* and gave significant serum reactions to *Bact paratyphosum B* H and O and also to salmonella group suspension, but these findings could not be expected to give any indication as to when the infection was contracted Search was made for a possible carrier among the other residents or visitors of the court The only persons against whom there was any suspicious evidence were Mr A B and Mrs C D Mr A B gave a history of having had a bad attack of diarrhœa 3–4 weeks previously This man was not ill at any time during the actual outbreak four specimens of fæces were examined and only one, collected on July 19, was positive His serum showed agglutinins with *Bact paratyphosum B* H suspension to a titre of 1/125 but a second examination of his blood was not made Repeated specimens of urine gave a negative result He had been in the last war, but could give no history of past inoculations Mrs C D was also found to be excreting *Bact. paratyphosum B* in the fæces on only one occasion No decisive evidence against either of these could be found It is clear that the sanitation of the court was crude and that, given a single case or carrier, infection of the water-supply was almost inevitable Whether all the remaining 19 cases were infected directly from the water or from personal contact cannot of course be determined The first cases were reported on July 10, the last case on July 31, so that some may have been secondary

Bacteriology—There is no doubt that the organism isolated from the water was *Bact paratyphosum B* This organism was isolated from samples of the well water collected on July 12, 15 18 and 21, and Aug 6 It is quite plausible that the water first became infected about three weeks previously, and thereafter remained so until all carriers or cases had been removed from the court

The infection in the water was certainly heavy Northampton isolated *Bact paratyphosum B* on three occasions Oxford reported the isolation of *Bact paratyphosum B* from nine out of twelve 5 ml quantities from the sample collected on July 18 —a sample which travelled for three days before reaching the laboratory Leicester isolated *Bact paratyphosum B* from as little as 0 1 ml of a sample of water collected on July 21 All three laboratories agreed that the organism isolated from the water was predominantly in the group phase, but type phase colonies were found in some samples after careful search, and Oxford reported "As the organism was in the group phase suitable subcultures had to be made to obtain the type phase When this was obtained it was found to have agglutinated to full titre with serum prepared against *Bact paratyphosum B* H and O" Northampton and Leicester used tetrathionate broth as the culture medium followed by plating out on to eosin brilliant green methylene-blue agar (Knox, Gell and Pollock in the press) Oxford used Kauffmann's brilliant-green bile tetrathionate broth At Leicester *Bact paratyphosum B* was isolated in nearly pure culture by the use of tetrathionate broth with a formula known to be considerably more inhibitory than Muller's or Schäfer's medium [1] It is interesting to note that the organisms from the fæces of persons who drank the water were also predominantly in the group phase, though in a few specimens the type phase predominated and in repeated specimens from the same patient the group phase might replace the type phase or vice versa The sera examined also showed some very high titres with salmonella group suspensions In one of the early cases the agglutinins were *Bact typhosum* O 1/50, H negative at 1/25, *Bact paratyphosum* B O 1/500, H 1/250 trace, salmonella group 1/25,000 The relative titres with *Bact paratyphosum B* H and salmonella group suspensions did not appear to be closely related to the predominance of type or group phase in the fæces of the same individuals

Fully authenticated outbreaks of water-borne paratyphoid B fever are rare In several outbreaks water has been strongly suspected,[2] but bacteriological confirmation has been lacking There is a report [3] of a small domestic outbreak in Schleswig-Holstein in which *Bact paratyphosum B* was found in water from a well supplying the household involved In the Brixworth outbreak the evidence of a water-borne infection is complete though the original source from which the water became infected could not be discovered

SUMMARY

An outbreak of paratyphoid fever at Brixworth is described, in which 21 out of 34 residents in a group of seven cottages built round a court containing a pump from a shallow well proved to be infected From its mode of onset and distribution the outbreak was thought to be water-borne This was confirmed by the isolation of *Bact paratyphosum B* from five different samples of the well water in three different laboratories The way in which the well became infected was not discovered, but there was ample opportunity for infection to have occurred by pollution of the ground in the vicinity.

We are indebted to Dr C B Hogg, superintendent of Kettering Infectious Diseases Hospital, for supplying us with information about the patients under his care

INSTRUCTIONS FOR MEASURING INSULIN —Dr S L Simpson has made a valiant attempt to minimise mistakes in the injection of insulin by means of diagrams of syringes on which the doctor marks on the barrel how far the piston should be withdrawn for so many units of insulin These have proved useful at Willesden General Hospital diabetic clinic and the diagrams are now published as a stiff four-page folder (H K Lewis 6*d*) Of course no card can replace personal demonstration, but it may serve well as an aide-memoire to the instructed patient The simplification has perhaps been carried too far as only one strength of insulin, 40 units per c cm , is mentioned

A WATER-BORNE OUTBREAK OF PARATYPHOID B FEVER

D J Jones
MB WALES DPH
MEDICAL OFFICER OF HEALTH FOR BRIXWORTH

P G H. Gell
MB CAMB
EMERGENCY PATHOLOGIST, PUBLIC HEALTH LABORATORY, NORTHAMPTON

R Knox, MD LOND MRCP
EMERGENCY PATHOLOGIST PUBLIC HEALTH LABORATORY, LEICESTER

In July 1941 there occurred in the village of Brixworth Northants, an outbreak of paratyphoid B fever which though small, was of interest because epidemiological inquiries led decisively to the conclusion that the source was an infected water-supply, and this conclusion was confirmed by the discovery on several occasions of *Bacterium paratyphosum B* in the water[1]

On July 10, four cases of enteric fever were diagnosed on clinical grounds in Brixworth The symptoms were frontal headache and diarrhœa of several days duration and the signs fever, sweating furred tongue and in three cases rose spots All were removed next morning to the isolation hospital The sera of all four patients showed agglutinins in high titre for *Bacterium paratyphosum B*, which was isolated from fæces and urine

All four patients were living in a group of seven cottages in Brixworth, but four different households were involved The water-supply was pumped from a well and shared by the inhabitants of the cottages Immediate instructions were given to all the residents to boil all water and milk until further notice. Bacteriological examination showed the milk to be satisfactory but a sample of the water collected on July 12 was heavily polluted and gave a fæcal coliform count of 1800 per 100 ml The pump handle was therefore chained on July 14 Next day a report was received from Northampton EPH Laboratory that from the sample of water collected on July 12 *Bact paratyphosum B* had been isolated In the meantime, blood samples had been taken from all adults living in the seven cottages ; four of these agglutinated *Bact paratyphosum B* H or salmonella group suspension to titres ranging from 1/50 to 1/250 All four were removed to hospital and were found to be excreting *Bact paratyphosum B* Two of them admitted to having had diarrhœa as the sole symptom within the previous 5–7 days Later it was found that one of these four, Mr A B, had had about 3 weeks previously an attack of diarrhœa which came on suddenly and lasted two or three days. On July 15 blood samples were taken from all of thirteen children living in the cottages Nine showed agglutinins to a significant titre with *Bact paratyphosum B* H or salmonella group suspensions Most of these children had had no symptoms, all nine were however removed to hospital, and were subsequently found to be infected by isolation of *Bact paratyphosum B* from their excreta Careful watch was kept on the remaining occupants of the cottages, and at intervals specimens of blood, fæces and urine were examined bacteriologically. In the next few days two married women and a girl, whose blood had previously shown agglutination to 1/50 with salmonella group suspension, were found either to be excreting *Bact paratyphosum B* in the fæces or to show significant agglutination with *Bact. paratyphosum B* H or salmonella group suspensions The son of one of these women was found to have paratyphoid B in a specimen of fæces taken on July 31 No further cases were discovered

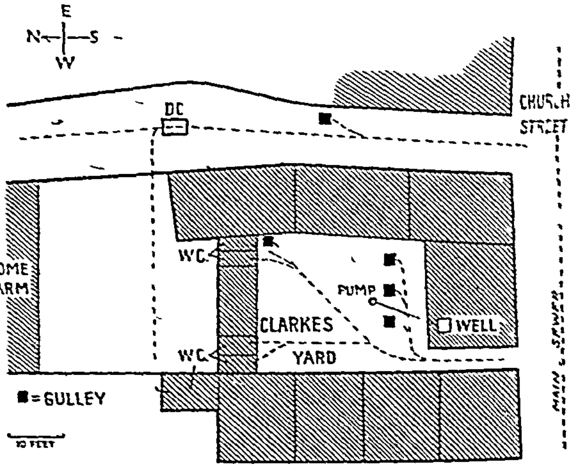
The population at risk in the cottages was 34, of this no fewer than 21 (in fact, all of those suspicious on clinical or serological grounds) were found at one time or another to be excreting *Bact paratyphosum B* in the fæces Only four of these can be described as typical clinical cases

SANITATION AND DRAINAGE

The area concerned in the outbreak was a group of seven houses Two of these had been the subject of action by the local RDC under the Housing Acts, and the owner had given an undertaking not to permit the houses to be used for human habitation The houses were however reopened for the reception of bombed-out families from London

The seven houses were grouped around a closed yard, the entrance to which was through a narrow alley way (see figure) The site was a good example of the old type of court The water-supply to these seven houses was from a pump at least 50 years old The water actually collected in a small brick chamber in the basement of one of the houses and was piped thence to the pump in the centre of the yard The well was approximately a 2 ft 6 in cube with a 2 ft depth of water in it, it lay 4–5 ft below ground level and had been subject to flooding from surface water in the yard during heavy rainstorms The distance from the well to the pump was 15 ft The well held 30–35 gallons of water It was very rapidly emptied taking half an hour to refill

The houses round the court were served by four hand-flushed closets The sewage from these discharged into pipes which ran within a few feet of the pipe connecting the well and the pump, and then passed out of the court in the line of the alley-way to enter a sewer under the roadway south of the court. The closets and drainage had been in existence at least 50 years according to one of the oldest residents There were in addition four gulleys which entered the drains at various points in the yard



Plan of the area in which the cases occurred.

As soon as *Bact paratyphosum B* was found in the water, the drainage of the area adjacent to the court was investigated From the diagram it can be seen that there were three possible sources from which the well might have been infected—the drainage of the farm on a slightly higher level to the north of the court, the drainage of the court itself, and the main sewer under the roadway Fluorescein tests suggested that all three systems might be defective, direct inspection showed defects in the first two sets of drains but the main sewer was not inspected That the source of infection was very close to the well is suggested by the fact that despite careful inquiry not a single case of infection was detected in the village apart from the inhabitants of the court The farm above the court can almost certainly be excluded, for repeated examination of blood, fæces and urine from its eight inhabitants yielded negative results In the village itself across the road from the court at a distance of 50–100 yards there were three wells which, after the fluorescein test, showed the colour of the dye This may have been due to a leak in the main sewer or possibly to an abnormally heavy fall of rain which occurred immediately after the test None of the consumers of water from these wells had any ill effects and all the families concerned were investigated with negative results It seems therefore most likely that the water in the well became infected from some point in the drainage system of the court itself

Action taken by the local authority—The main features of the action taken by the local authority in controlling the outbreak were as follows

---

[1] Epidemiological inquiries were made by one of us (D J J) with the help of the Brixworth sanitary inspectors and later of Dr Fleming of the American Red Cross and in consultation with the regional medical officer of the Ministry of Health and Dr Smith, county medical officer The laboratory work was carried out at the Emergency Public Health Laboratories at Northampton and Leicester in addition, one sample of water was examined at the EPH Laboratory at Oxford

(1) Careful supervision of the population at risk, including occasional week end visitors of the evacuee families Communications were sent to the medical officers of health of the areas in London where the persons resided and they were followed up there with negative results

(2) Fullest use of laboratory facilities and close collaboration with the laboratory workers

(3) Immediate removal to hospital of all ascertained cases, including many that would not have been diagnosed at all without strict and repeated bacteriological control

(4) Preliminary instructions on July 10 to boil all water and milk, followed on July 14 by cutting off the water supply By July 18 main water-supply was laid on to the houses of the court, taps being installed in the yard

(5) Relaying of all defective drainage in the properties concerned

SOURCE OF THE OUTBREAK

The only factor common to the inhabitants of the court and not shared by the rest of Brixworth was the water-supply, which for this reason alone was strongly suspected from the start Bread and milk could be dismissed as possible sources of the outbreak ; blood and two samples of fæces and urine from all the staff of the bakery and dairy supplying the court were investigated, with negative results Suspicion of the water was strengthened by the very high proportion of cases among the population at risk (21 out of 34), and by the fact that no cases occurred in the rest of the population of Brixworth, a village of some 2000 inhabitants The isolation of *Bact paratyphosum B* from the water collected on July 12 completed the chain of evidence

The method by which the water became polluted can only be guessed at Several recent cases of paratyphoid B fever in the neighbourhood had to be considered Earlier in the year there had been a small outbreak in a residential school 6 miles to the east Three weeks before the outbreak in the court a sporadic case occurred in a village 2 miles to the west and almost at the same time a case was notified in a village 6 miles to the north. No connexion between any of these cases and the outbreak in the court could be traced Careful inquiries showed that five of the patients in the court had had attacks of diarrhœa in April These may have been the result of some non-specific pollution of the well but it is possible that they were mild cases of paratyphoid fever and that one or more of them had continued in the carrier state up to July Laboratory examinations in July showed that all of these five were excreting *Bact paratyphosum B* and gave significant serum reactions to *Bact paratyphosum B* H and O and also to salmonella group suspension, but these findings could not be expected to give any indication as to when the infection was contracted Search was made for a possible carrier among the other residents or visitors of the court The only persons against whom there was any suspicious evidence were Mr A B and Mrs C D Mr A B gave a history of having had a bad attack of diarrhœa 3–4 weeks previously This man was not ill at any time during the actual outbreak four specimens of fæces were examined and only one, collected on July 19, was positive His serum showed agglutinins with *Bact paratyphosum B* H suspension to a titre of 1/125 but a second examination of his blood was not made Repeated specimens of urine gave a negative result He had been in the last war, but could give no history of past inoculations Mrs C D was also found to be excreting *Bact. paratyphosum B* in the fæces on only one occasion No decisive evidence against either of these could be found It is clear that the sanitation of the court was crude and that, given a single case or carrier infection of the water-supply was almost inevitable Whether all the remaining 19 cases were infected directly from the water or from personal contact cannot of course be determined The first cases were reported on July 10, the last case on July 31, so that some may have been secondary

Bacteriology —There is no doubt that the organism isolated from the water was *Bact paratyphosum B* This organism was isolated from samples of the well water collected on July 12 15 18 and 21, and Aug 6 It is quite plausible that the water first became infected about three weeks previously, and thereafter remained so until all carriers or cases had been removed from the court

The infection in the water was certainly heavy Northampton isolated *Bact paratyphosum B* on three occasions Oxford reported the isolation of *Bact paratyphosum B* from nine out of twelve 5 ml quantities from the sample collected on July 18 —a sample which travelled for three days before reaching the laboratory. Leicester isolated *Bact paratyphosum B* from as little as 0 1 ml of a sample of water collected on July 21 All three laboratories agreed that the organism isolated from the water was predominantly in the group phase, but type-phase colonies were found in some samples after careful search, and Oxford reported "As the organism was in the group phase suitable subcultures had to be made to obtain the type phase When this was obtained it was found to have agglutinated to full titre with serum prepared against *Bact paratyphosum B* H and O " Northampton and Leicester used tetrathionate broth as the culture medium followed by plating out on to eosin brilliant green methylene-blue agar (Knox, Gell and Pollock in the press) Oxford used Kauffmann's brilliant-green bile tetrathionate broth At Leicester *Bact paratyphosum B* was isolated in nearly pure culture by the use of tetrathionate broth with a formula known to be considerably more inhibitory than Muller's or Schäfer's medium [1] It is interesting to note that the organisms from the fæces of persons who drank the water were also predominantly in the group phase, though in a few specimens the type phase predominated and in repeated specimens from the same patient the group phase might replace the type phase or vice versa The sera examined also showed some very high titres with salmonella group suspensions In one of the early cases the agglutinins were *Bact typhosum* O 1/50, H negative at 1/25, *Bact paratyphosum B* O 1/500, H 1/250 trace, salmonella group 1/25,000 The relative titres with *Bact paratyphosum B* H and salmonella group suspensions did not appear to be closely related to the predominance of type or group phase in the fæces of the same individuals

Fully authenticated outbreaks of water-borne paratyphoid B fever are rare In several outbreaks water has been strongly suspected [2] but bacteriological confirmation has been lacking There is a report [3] of a small domestic outbreak in Schleswig-Holstein in which *Bact paratyphosum B* was found in water from a well supplying the household involved. In the Brixworth outbreak the evidence of a water-borne infection is complete though the original source from which the water became infected could not be discovered

SUMMARY

An outbreak of paratyphoid fever at Brixworth is described, in which 21 out of 34 residents in a group of seven cottages built round a court containing a pump from a shallow well proved to be infected From its mode of onset and distribution the outbreak was thought to be water-borne This was confirmed by the isolation of *Bact paratyphosum B* from five different samples of the well water in three different laboratories The way in which the well became infected was not discovered, but there was ample opportunity for infection to have occurred by pollution of the ground in the vicinity.

We are indebted to Dr C B Hogg, superintendent of Kettering Infectious Diseases Hospital, for supplying us with information about the patients under his care

INSTRUCTIONS FOR MEASURING INSULIN —Dr S L Simpson has made a valiant attempt to minimise mistakes in the injection of insulin by means of diagrams of syringes on which the doctor marks on the barrel how far the piston should be withdrawn for so many units of insulin These have proved useful at Willesden General Hospital diabetic clinic and the diagrams are now published as a stiff four-page folder (H K Lewis 6*d*) Of course no card can replace personal demonstration, but it may serve well as an aide-memoire to the instructed patient The simplification has perhaps been carried too far as only one strength of insulin, 40 units per c cm , is mentioned

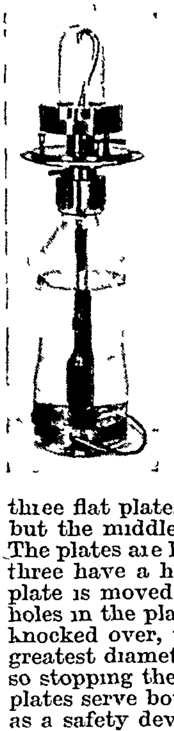
PORTABLE APPARATUS FOR CONTINUOUS INTRAVENOUS THERAPY

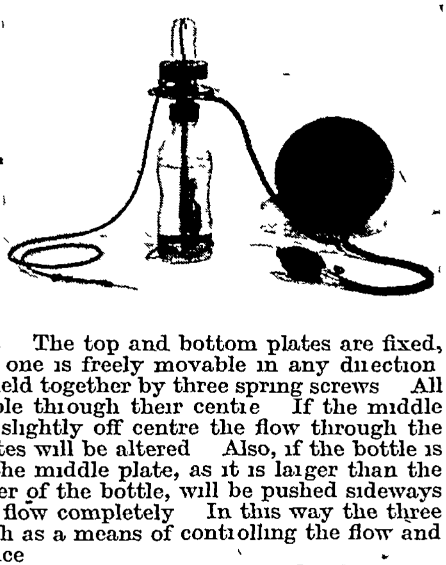
B G B Lucas, M R C S, D A   A L Sims
ACTING SQUADRON LEADER R A F V R

The apparatus described in this paper was designed primarily for the continuous administration of intravenous anæsthetic solutions, but it can also be used for the intravenous injection of blood or other fluids Of the many forms of apparatus in use, none appear completely satisfactory An inverted reservoir on a stand is clumsy and easily knocked over, whereas if positive pressure is used the apparatus tends to leak Again, the rubber parts of most machines perish rapidly with continual sterilising, and constant replacements are necessary

It was finally decided that an intravenous apparatus must be portable and not occupy any more space than is absolutely necessary (this ruled out a gravity feed in favour of some form of positive pressure apparatus), it must be completely safe so that under no circumstances can air be injected into the patient, even if the bottle is knocked over accidentally or becomes empty, it must fit a standard bottle (the EMS blood-transfusion bottle was chosen as the standard), it must be reliable, robust and hard-wearing, have an adjustable and clearly visible drip feed, and be easy to sterilise In order to meet the need for hard wear we decided to reduce glass and rubber to a minimum, and to build the apparatus of metal Brass was chosen for its easy machinability and cheapness of manufacture All metal parts were afterwards silver-plated

The apparatus[1] (see figures) consists of a screw cap through which passes a long tube reaching to the bottom of the bottle At the lower end of this tube is incorporated a float valve which, by its own weight, will cut off the supply of liquid when the bottle is nearly empty The float being hollow normally rests against the upper screw, but when the bottle is empty it falls, sealing the rubber opening The flow is controlled by a system of three flat plates The top and bottom plates are fixed, but the middle one is freely movable in any direction The plates are held together by three spring screws All three have a hole through their centre If the middle plate is moved slightly off centre the flow through the holes in the plates will be altered Also, if the bottle is knocked over, the middle plate, as it is larger than the greatest diameter of the bottle, will be pushed sideways so stopping the flow completely In this way the three plates serve both as a means of controlling the flow and as a safety device





The glass drip bulb is a ‘ Pyrex ’ test-tube chosen for its strength and ease of replacement This is held in place by a rubber gland, compressed by a surrounding hand nut In course of time the rubber perishes and tends to leak, the gland can then be further compressed, so keeping the junction air-tight Apart from the rubber washer inside the cap which fits on the bottle, the only other perishable part of the apparatus is the rubber seat of the float valve This, however, is merely a short piece of ordinary rubber tubing and can easily be replaced Positive pressure is supplied by a small hand bellows, a football bladder acting as an air reservoir The bladder was adopted because it permits enough reserve of pressure to last a whole bottleful The remainder of the apparatus, the outlet tubing and intravenous needle, are similar to those on the usual drip transfusion apparatus

The apparatus is sterilised by boiling for 20 min in the usual way It is then screwed on to an ordinary EMS transfusion bottle in which is placed the desired anæsthetic solution

This apparatus has been tested and used over a considerable period and in our opinion greatly simplifies intravenous anæsthesia It is completely reliable and foolproof and can be easily cleaned and sterilised When not in use it is left on the shelf and is boiled up only when required

PREPARATION OF ANTISCORPION SERUM

USE OF ATROPINE AND ERGOTOXINE

Ahmed Hassan Mohammed, PH D CAIRO
(Physiological Laboratory, Faculty of Agriculture, and Biochemical Laboratory, Faculty of Medicine, Fouad I University)

In an unpublished MSc thesis in 1937 I described the preparation of a crystalline toxin from a mixture of the poisons of the three most common Egyptian scorpions, but chiefly that of *Buthus quinquestriatus* This was a secondary proteose which caused both sympathetic and parasympathetic stimulation Its main effects were (*a*) inhibition of smooth muscle, (*b*) acceleration of the isolated heart (antagonised by ergotoxine), (*c*) rise of blood-pressure (reversed by ergotoxine), (*d*) hyperglycæmia and glycosuria, (*e*) vomiting and contraction of the intestine and bladder in the intact animal (antagonised by atropine)

The effects of poisoning by the toxin in rats can thus be combated by the use of either atropine or ergotoxine alone or more effectively by a combination of the two drugs

I have since made some further observations (unpublished PhD thesis in 1939) These show that the scorpion toxin has a specific absorption band (crude 260μ, pure 278μ) The different toxins and venoms obtained from four species—*B quinquestriatus*, *B leptochelys*, *B acutecarinatus* and *B hottentotta minax*—gave the same band This band is a direct indication of the potency of the toxin or venom solutions as affected by reagents or temperature Thus dilute alkali, acetaldehyde and formaldehyde inflect the band and diminish the toxicity Scorpion toxin produces the same rise of blood-pressure whether the animal injected with it is adrenalectomised, spinal or spinal adrenalectomised It also acts in exactly the same way as adrenaline on blood vessels, whether they are innervated or denervated, ergotinised or not—in other words, the toxin is a vasoconstrictor to either innervated or sympathectomised blood-vessels That is, it acts on the blood-vessels themselves as well as on their sympathetic nerve supply It can be concluded from these experiments that the toxin directly stimulates the nerve-endings of the autonomous system without selection

I have shown that in dogs, though neither atropine nor ergotoxine alone is effective, a mixture of the two drugs prevents the onset of symptoms, and that ergotamine tartrate (‘ Femergin ’ Sandoz) can effectively replace this mixture For a dog 1 m l d is 0 03 mg per kg, and for an animal weighing 6 kg 2 m l d is therefore 0 36 mg of toxin A mixture of atropine and ergotoxine protected a dog from this dose, which is large compared with the amount which can be delivered by a scorpion at a single strike A fully grown specimen of *B quinquestriatus* excited and made to strike seven times through a rubber membrane yielded only 0 5 mg of toxin Another scorpion of the same species made to strike three times gave only 0 2 mg and by electrical stimulation of a living specimen 0 6 mg of toxin was obtained Since in the majority of cases the victims are only struck once it should be possible to prevent the occurrence of symptoms either with a mixture of atropine and ergotoxine or better still with ergotamine tartrate

In the preparation of antiscorpion serum, formol toxoid (Shousha[1]) has been used for the early stages of active immunisation In the present paper it is shown that toxin may be used from the outset if the toxic effects are masked by the use of atropine and ergotoxine or ergotamine tartrate, or much better by using femergin and 'Bellafoline' (Sandoz) together

[1] Shousha, A T *Congr int Méd trop*

EXPERIMENTAL FINDINGS

In dogs —Fourteen dogs were immunised in the course of 5½ months by subcutaneous injections of toxin at 5-day intervals In seven the symptoms of the early doses were masked by the simultaneous injection with each dose of toxin of 0 033 mg atropine per kg and 0 005 mg ergotoxine per kg, and in the remainder by 0 04 mg per kg of ergotamine tartrate per kg By the time the animals had become actively immune to 5 m l d (0 165 mg toxin per kg) it was no longer necessary to use the pharmacological antagonists to protect them After some loss of weight in the early stages the animals returned to their early weight and remained in good condition throughout One dog after this course of immunisation was immune to 150 m l d and another to 55 m l d

In these dogs the antitoxic titre of the serum was tested by the method of Shousha,[1] various quantities of serum being added to 2 m l d of toxin, incubated for an hour and injected subcutaneously into albino rats weighing 100 g The m l d for rats of this weight is 0 02 mg of toxin Rats which received mixtures containing 0 4, 0 2, 0 1 0 066 and 0 05 c cm of serum from one of the immunised dogs survived, whereas those receiving 0 04 and 0 033 c cm of serum died, 1 c cm of serum would therefore neutralise at least 40 rat m l d s

In rabbits —Twelve rabbits were immunised by subcutaneous injection of toxin in the same manner In six 0 4 mg atropine per kg and 0 03 mg ergotoxine per kg, and in six 0 5 mg of ergotamine tartrate per kg was given subcutaneously with the toxin for the first twelve injections The injections were given at intervals of 5 days

Rats injected with mixtures of 2 m l d of toxin incubated with 0 2 to 0 033 c cm of serum from a rabbit immunised with toxin plus ergotamine tartrate survived, whereas those receiving mixtures containing 0 028 and 0 025 c cm of the same serum died The serum of this rabbit therefore neutralised 60 rat m l d s of toxin per c cm

In goats —Six goats were immunised by subcutaneous injection of toxin, and for the first twelve injections three were protected with atropine and ergotoxine and three with ergotamine tartrate They were then receiving 10 mg of toxin, and 4 months later without any further antidote treatment they were all immune to 175 mg of toxin The serum tested in the laboratories by Dr H Ibrahim of the ministry of health was found to be much stronger than that issued from the Lister Institute, 1 c cm neutralising up to 130 m l d for 100 g rats

With the object of employing a belladonna derivative of constant qualities bellafoline was employed instead of atropine Bellafoline combined with femergin gave better and quicker results Two goats were immunised by subcutaneous injection of toxin, and for the first four injections were protected with bellafoline and femergin They were then receiving 20 mg toxin, and 1½ *months* later without any further antidote treatment they were both immune to 200 mg of toxin The serum, tested in the laboratories of the Agouza Serum Department of the Ministry of Health, was found to be highly potent

CONCLUSIONS

If the sympathetic and parasympathetic nervous systems are first paralysed with atropine and ergotoxine or with ergotamine tartrate lethal doses of active scorpion toxin can then be injected without harm

Neither of these antidotes interferes with the antigenic power of the active toxin, and dogs, rabbits and goats injected with active toxin plus antidote acquired a high degree of immunity

This procedure might be used in the preparation of antiscorpion serum from horses

I wish to express my gratitude to Prof G V Anrep for his interest, to Prof Ali Hassan for his personal guidance, and to Dr M Talaat for help in the physiological experiments

A CASE OF *P FALCIPARUM* MALARIA

J ELLIOT MURRAY, M D EDIN
CONSULTING PHYSICIAN TO AN
EMS HOSPITAL

P G SHUTE, F R E S
ASSISTANT MALARIOLOGIST TO
THE MINISTRY OF HEALTH

WAR and malaria are inseparable allies, and when there is a war in almost any part of the world where the isotherm is over 60° F malaria is likely to be an important medical and entomological problem During the last decade many important facts about the epidemiology of malaria have become known

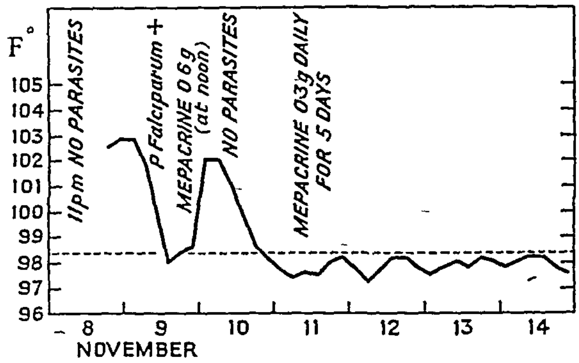
Plasmodium falciparum causes malignant tertian malaria, in which larger doses of quinine are usually necessary to cure an attack than with the other types of malarial infection Although the primary attacks are usually very severe, relapses are less common than they are with at least two other species, and a relapse seldom, if ever, occurs after the ninth month from the time the infected person leaves an endemic area *P falciparum* malaria is a tropical and subtropical disease and it is not endemic where the summer isotherm is much below 70° F, while *P vivax* (benign tertian) may be endemic with an isotherm of 60° F It seems that so far in this war malaria has not affected British troops to the same extent as during the last war, but our overseas forces are for the most part in the *P falciparum* belt and this parasite causes a higher mortality than either *P vivax*, *P ovale* or *P. malaria* It may therefore bring considerable anxiety to the medical authorities

In primary infections due to *P vivax*, over 85% of cases have quotidian fever with temperatures varying between 103° F and 106° F In untreated attacks the fever may continue for about a fortnight and then, even without antimalarial drugs, the tendency is towards a spontaneous recovery In relapses over 90% of the cases develop the classical tertian type of fever, and provided that the patient is confined to bed the fever usually disappears spontaneously after three or four attacks, probably depending on the number of attacks during the primary illness But parasites often persist for weeks after the cessation of fever and unless such cases are treated they will develop severe anæmia Even in acute primary cases of *P falciparum* the temperature often fails to rise above 102° F or 103° F On the other hand with *P vivax* infections a single attack seldom lasts for more than 10 hours and at the end of the attack the temperature falls rapidly to subnormal In *P falciparum* the temperature often remains above normal for several days, probably owing to successive segmentation of parasites at short intervals Recently a case has come under our care

CASE-HISTORY

An Army officer had been living in West Africa for 9 months He fell sick while in Africa and was admitted to hospital There was no previous history of malaria, but in August, 1941, he had been treated for bacillary dysentery, in September there was a gradual onset of pain in the right iliac fossa, aching in character and remittent The pain increased, and on his admission to hospital there was some tenderness in the right iliac fossa but no fever or vomiting He was constipated and there was a history of chronic indigestion His blood was examined for malarial parasites several times but always with a negative result He had begun taking quinine, gr 10 daily, on his arrival in Africa and continued until a few days after his return to England X rays showed nothing abnormal in the renal tract An opaque meal showed a filling defect about the size of a walnut in the medial cæcal wall just above the iliocæcal valve, fixed and with acute local tenderness The appendix was well filled, mobile and not tender The findings were consistent with retrocæcal abscess or malignant disease He was considered to be in need of urgent medical treatment so he was sent to England by air, and arrived on Oct 26, 1941

On admission to an English EMS hospital he looked rather sallow, his tongue was slightly furred, and his liver enlarged and tender, the spleen was not palpable He had tenderness along the ascending colon, the point of maximum tenderness being just about the cæcal area, there was hyperæsthesia to pin prick over this area On the day after admission a barium enema was given The barium passed through the colon freely to the ascending colon, this part of the colon was extremely irritable, filling and emptying periodically throughout the examinations the cæcum was not outlined The fæces showed no mucus or pus Cultures produced a profuse growth of *Streptococcus fæcalis* and staphylococci, Morgan's bacillus was isolated While at home on a week end pass he collapsed and had a rigor followed by profuse perspiration, pains in the limbs and severe pain in the right loin He was brought back to hospital His temperature on admission was 102° F, pulse rate 104 per min



Thick and thin blood-films were examined for an hour but no malaria parasites were found The question arose as to whether an antimalarial drug should be given in view of the clinical picture but it was decided to wait until the temperature fell and then examine further films Next day films were again examined and after a 50 min search of a thin film one parasite was found, 2 very small merozoites were suspected in a thick film The parasite found in the thin film was very minute (an accole form) The films were stained with Leishman as described by James[1]

The patient was given 0 6 g of mepacrine by mouth and 48 hours later a dose of 0 3 g daily for 5 days On Nov 20, 10 days after his attack of malaria, a barium meal was given and it was found that the cæcum filled normally There was no evidence of growth or other abnormality The enlargement of the liver disappeared and there was no tenderness over the cæcum or ascending colon At a subsequent medical board, the officer was graded A1

Up to date, ten months later, there have been no further attacks, either clinical or parasitological, and no further anti malarial drugs have been administered

COMMENT

A peripheral blood-film examination carried out at the height of an attack of *P falciparum* malaria failed to reveal parasites The illness is now believed to have been a straightforward uncomplicated case of *P falciparum* malaria We believe that it is unlikely that even a large dose of quinine, given orally, would have cured the attack as dramatically as did mepacrine (see figure)

It is not surprising that in Africa no malarial parasites were found, in view of the fact that, according to the patient, he was taking his daily dose of quinine all the time he was in hospital If on admission to the African hospital, quinine had been discontinued an attack of fever would probably have developed, as happened when he ceased taking quinine on his return to England, parasites would soon have appeared in the peripheral blood and a diagnosis of malaria would have been made As it was the daily dose of quinine was keeping the parasites at such a low level as to make it almost impossible to find them

Non-Pulmonary Tuberculosis

MICHAEL C WILKINSON, MB Lond, medical superintendent, Essex County Hospital, Black Notley London Hamish Hamilton Medical Books Pp 174 *12s 6d*

THIS book is based on Dr Wilkinson's experience in the investigation and treatment of 593 patients with all forms of non-pulmonary tuberculosis over a period of seven years His views coincide with those of others that the prognosis of non-pulmonary tuberculosis is largely dependent upon associated lesions and their multiplicity, that the disease runs a long course and one that is, to a certain extent, self-limiting, and that constitutional and conservative treatment must be applied first, operation being postponed until the disease is quiescent In his account of the pathogenesis the evidence in favour of a blood-stream infection is convincingly marshalled The salient points in constitutional treatment—open-air, rest for both patient and part, good food and sunlight—are accorded a separate chapter In considering the various forms of non-pulmonary tuberculosis individually he has used tables adroitly to show the incidence of associated lesions and the results of treatment

It is a commentary upon our time that the section dealing with the signs and symptoms of tuberculosis of the spine begins and ends with the radiological features thus the clinician's dependence upon the X-ray plate is as complete in the non-pulmonary as in the pulmonary manifestations of tuberculosis Nevertheless, the general reader would welcome a brief reference to the more purely clinical symptoms and signs in order that he may help to prevent those late admissions to sanatoriums which Dr Wilkinson mentions

The Autonomic Nervous System

(2nd ed) JAMES C WHITE, MD chief of neurosurgical services, Massachusetts General Hospital, REGINALD H SMITHWICK, MD, assistant visiting surgeon to the hospital London Henry Kimpton Pp 469 *35s*

DR WHITE has obtained the help of his colleague, Dr Smithwick in the task of rewriting his book, but those who knew and valued the first edition will be glad to find that the general pattern of the work is unaltered Every chapter shows signs of careful revision and amplification Surgical technique has been influenced both by the incomplete success of the earlier sympathectomies and by the results of physiological experiments, and the new operations, particularly for Raynaud's disease and for hyperpiesia together with the evidence given in support of their efficacy, have special interest The greater part of the book deals with the anatomy physiology, and clinical investigation of the autonomic system and its disorders and is of equal interest to physicians and surgeons The chapters on visceral pain, and particularly that on angina pectoris, are to be commended, though renal pain and its relief by sympathectomy is given rather less attention than the subject deserves There are more and better anatomical diagrams than in the first edition, but the illustrations of operations are still unworthy of a book pre-eminent in relating the autonomic nervous system to clinical medicine

Companion to Manuals of Practical Anatomy

(5th ed) E B JAMIESON, MD Edin London Humphrey Milford, Oxford University Press Pp 734 *15s*

THE fifth edition of this good and authoritative handbook can be used by students with manuals of practical anatomy, as intended originally or to replace in some ways the regular use of textbooks The section dealing with the central nervous system is still the most important part of the book, and the work is invaluable for occasional reference about detail, when it will spare the busy doctor a fatiguing search among larger works and textbooks

The Blood in Cancer

O CAMERON GRUNER, MD Lond Montreal, Renouf Publishing Co, London H K Lewis Pp 100 *15s*

IN this book, morphological changes and variations in the constituents of the blood in cancer are described in great detail, and illustrated by figures and colour plates It is not claimed that in cancer any specific or pathognomonic signs are to be found in the blood, but Dr Gruner believes that a pattern of changes forms a guide to diagnosis The alterations are recorded in pictorial form on charts from which the idea of a pattern is derived

BIOCHEMICAL SOCIETY —A meeting of this society will be held in the Department of Biochemistry, South Parks Road, Oxford, on Saturday, Sept 26, at 11 30 A M

THE LANCET

LONDON SATURDAY, SEPTEMBER 26, 1942

STAPHYLOCOCCAL NURSERY

MEDICAL officers of maternity institutions, more particularly those emergency homes adapted for expectant mothers evacuated from the larger towns, have been impressed with the increasing frequency of staphylococcal infection among the babies These infections may take a variety of forms—blepharitis, septic spots and paronychiæ, pemphigus, pneumonia and so on—and there is a strong tendency for each of them to breed true for instance, pemphigus neonatorum and staphylococcal pneumonia seldom occur in the same outbreak in spite of the fact that the frequent involvement of the face in pemphigus would seem to favour an aerogenous pneumonia Blepharitis or "sticky eyes" is the commonest form of staphylococcal infection among the newborn, and although it has often been noted as a precursor or accompaniment of pemphigus there is not necessarily any close connexion between the two infections Most infants are unaffected by the blepharitis, which usually clears up quickly and is unassociated with skin infection Septic spots and paronychiæ may affect several infants within a short period, suggesting a case-to-case spread, and according to CASS[1] the infections often coincide with the development of colds among the mothers These superficial follicular pustules do not disturb the child's general health but must be distinguished from the dull red papular rash of generalised sepsis or the septic spot which is really a subcutaneous abscess

Pemphigus neonatorum or bullous impetigo is characterised by the formation of dome shaped bullæ with clear straw-coloured contents, the blebs rupture and desquamate readily, leaving red, moist, glistening patches which heal quickly Sometimes desquamation occurs without vesicle formation and may be widespread, when the condition is called Ritter's disease or exfoliative dermatitis of infants Many outbreaks of pemphigus neonatorum have been described, and there is now general agreement that *Staphylococcus aureus* is the causative organism BENIANS and JONES,[2] who reviewed the essential features of the infection, failed to substantiate Almquist's claim that the pemphigus staphylococcus had distinguishing cultural characters, although FALLS[3] and others showed that it differs from other staphylococci in producing vesicular lesions when inoculated into man, and there is little doubt that nurses can be secondarily infected from infants The primary source in any nursery outbreak is to be looked for particularly in skin lesions among mothers or nursing-staff Routine swabbing of nose and throat is of little value, because over 90% of infants in nurseries are likely to be nasal carriers of *Staph aureus* and the carrier-rate among nurses may vary from 20% to 50% Nor is examination of the mother's milk likely to help, for more than half the milks from nursing mothers contain *Staph aureus*[4] Unfortunately serological typing of the staphylococcus is still a research, and the number of differentiated types is too small to allow conclusive deductions about sources to be drawn from this technique[5] We must therefore try to discover the factors which predispose to outbreaks of pemphigus and devise methods for the control of an outbreak when it occurs

The high incidence in emergency maternity homes may be associated with difficulties of adequate staffing and isolation accommodation Cheap soaps are apt to be irritating and should be avoided for washing babies, more use being made of oils for rubbing into the skin But the most important precaution is to keep a sharp lookout for any skin lesion on infant, mother or nurse, and treat it at once with 5% sulphathiazole ointment or "blue paint" (pigmentum tinctoreum *NWF*), preferably under bed-isolation conditions When an outbreak occurs, the wisest course is to close the home to new cases until infected and exposed infants have all been discharged and the home has been thoroughly cleaned and disinfected, for the infecting staphylococcus may persist in the dust Anything short of this, such as isolation of infected infants, wearing of masks and disinfection of baths or of the wards, may fail to check the spread of infection[6] Fortunately the infection in most recent outbreaks has been mild and fatalities have been rare

MORALE

SOME say that morale, like marriage, friendship and good neighbourliness, is an interhuman phenomenon which gets along all right as long as one does not talk about it Our own morale has remained high for the last three years under grave adversities, but its hardest test may still be to come, we should therefore think of all possible ways of maintaining it, and there can be no harm in discussing it as a problem in social psychology The term morale is vaguely used by political speakers and writers, and is variously defined even by psychologists According to MCDOUGALL[7] "group spirit" depends on each individual member having a clear knowledge of the group and his place in it as well as a devotion to the group This shows the double aspect of morale, one intellectual and one emotional, practical measures to maintain it will be influenced by which aspect is considered more important

VERNON[8] has studied a number of human qualities generally regarded as linked with morale to find how far they are interrelated in the psychological make-up of the individual He chose 17 qualities intelligence, cheerfulness, stubbornness, considerateness, determination, openmindedness, adaptability, tolerance, idealism, acceptance of hardship without complaint, constructiveness, stolidity, trustfulness in leaders, optimism, stability, health and vitality, and self-confidence He asked a group of psychologists and senior students to rate themselves and their acquaintances on these qualities according to a scale which gave three major degrees for each quality. Self-confidence, for example, was graded as (a) outstandingly confident and well adjusted in all phases of life, (c) generally confident but some anxieties or minor maladjustments, (c) anxious, worrying, timid in personal and social adjustments, (b) and (d) represented intermediate shades of difference In this way 50 ratings of professional people, such as the raters themselves, schoolteachers or their relatives were collected The same assessors were then given records of interviews with a group of 23 people unknown to them—mostly factory workers, small shopkeepers and the like—and asked to rate them on the same scale The interviews had been carried out by trained interviewers in an endeavour to ascertain attitudes to the war Since each of these records was assessed by two or three people the total number of ratings in this group was also 50 The findings in the two groups differed in some respects, thus the raters, who themselves belonged to the professional group, laid stress on the value of a rational, liberal, altrocentric outlook, which, though present in both groups, was more common among the professional subjects Nevertheless they found an underlying common factor in both groups, made up of qualities which seem to hang together, the chief being confidence, optimism, trustfulness, resistance to hardship and cheerfulness This general factor, it is interesting to note, was more easily recognisable among the interviewed group than among those with whom the assessors were well acquainted, as though in order to form snap judgments of people it is necessary to know them superficially rather than well

The investigation had the disadvantage, of course, of being based largely on opinions, not on behaviour In a later inquiry into war attitudes VERNON[9] sent out a questionnaire asking people not only for their views on current political issues, but about their war-work, savings, hardships, newspaper reading and other war activities This was answered in April, 1941, by 230 subjects who, though not representative of the general population, showed a wide range of income, education and age Their human background, sex, age, economic level and education were taken into account and correlated with their reactions to the war Many of the results could have been anticipated, but the wide variations are striking and so is the strong evidence against over-simplified labels, like "reactionary," "complacent," "defeatist," which we are inclined to apply to other people With regard to morale, knowledge and education appeared to act in the same direction as personal bombing experience both make people more critical, and reduce irrational opinions, yet both may lead to greater war effort and good citizenship This work is relevant to the theoretical views of JOSEPH GEOGHEGAN[10] who stresses the emotional aspect of morale to the exclusion of all others "Morale is a feeling, not an intellectual opinion" Suggestibility, reduction of individuality, reversion to impulse and action of a more primitive type, childish pattern of behaviour—all well known clichés from LE BON's *Psychology of the Masses*—are for him the mechanisms underlying morale. Factors increasing morale are therefore, in his view, a sense of unity, comradeship, and belief in positive ideals on our own side, coupled with negation of all good on the enemy's Fatigue, under-nutrition, fear, inertia, monotony and inactivity exert a depressive influence on morale He doubts whether the positive factors can be deliberately influenced, but thinks the problem deserves attention, especially in regard to "the shifting unstable masses of a civil population exposed to novel and dangerous stresses" This remark sounds rather out of touch with reality in view of the response of people in our bombed cities, but it would be a mistake to brush aside GEOGHEGAN's views as a whole as out of date, and it would be a misleading over-simplification to call the morale he describes as the "German type," and to contrast it with the more critical and more intellectual British group spirit The attitudes of the French, before their collapse, were probably as rational and critical as our own, the collapse itself followed an entirely emotional pattern Nazi morale, which from outside seems to be built entirely on emotion, mass suggestion and herd instinct, has still to stand the test of adversity But German internal propaganda does not rely on emotion alone GOEBBELS likes to tell his countrymen that they are the best informed and most intelligent people in the world British morale in this war is still predominantly rational and intellectual—widespread and fantastic rumours have been rare, and blind fervour, emotional propaganda, and any stirring up of hatred have been widely criticised If those who support the war in the hope that it will lead eventually to a more rational and democratic organisation of society are still a minority, they are as VERNON points out more numerous and more vocal than in any past wars It should make the task of those who have to care for our morale easier if they can work on intellect and reason instead of playing on emotions How to do it without upsetting the emotional side of morale, which is probably more vulnerable because less vocal in this war, would be worth studying

THE SPECIALIST IN THE FORCES

THE practice of medicine in the Forces has been criticised repeatedly and defended as often, but few writers have dealt with specialist work A large number of specialists in the Forces are young men at the beginning of their careers, and although a few are idle most are doing some work Unless they are very unreceptive these young specialists are learning important and invaluable lessons, the physicians not much less than the surgeons There is no way of shirking decisions in the Forces as there is in civil life, this may not be the general impression, but it is so When a man is sent to a specialist there is no dodging the problem, the specialist must make up his mind clearly and definitely about diagnosis, treatment and disposal, and his advice must bear a realistic relationship to circumstances He cannot always be right, but he is learning to make decisions on clinical grounds—almost a lost art—and with increasing experience and confidence the number of errors falls. Gone are the happy days of vague phrases and liquid placebos The bureaucratic mind demands a label, a recognised standard name for every lesion, and it is thus unconsciously forcing the younger generation to think clearly and precisely about its clinical problems, forcing it to give up woolly thinking or writing pompous reports designed to hide a complete absence of ideas In military hospitals, too, the highly trained nursing staff of civilian hospitals is largely replaced by unskilled personnel Young specialists working in well-staffed highly systematised hospitals take for granted a large amount of hospital work and organisation without knowing how it is done The physician orders various nursing treatments without knowing in detail how to do them himself , or the surgeon walks into the theatre, dons his sterile gloves and proceeds to operate without any idea of how to sterilise those gloves or how to prepare that theatre In the Forces they are brought face to face with these fundamental problems No longer does the surgeon waste his time on academic discussions of the hundred-odd operations for recurrent dislocation of the shoulder-joint , he is too busy learning how to work the autoclave or cut swabs or rub plaster, in order to train his orderlies correctly This training is ample recompense for the slowing down of clinical and technical development But perhaps the most useful feature of medical practice in the Forces is the opportunity it gives for acquiring an improved knowledge of prognosis Under the civilian system the hospital staff rid themselves of the patient as soon as they can, and learn at second hand if at all how long he takes to recover fully, while the practitioner is often left to cope under unsuitable conditions with a patient who really needs longer hospital treatment and supervision This situation does not arise in the Forces, because it is useless sending an unfit man back to his unit He is a burden to himself and everyone else, and must be retained by the medical services until he is fit This has brought some nasty surprises, but the ultimate effect on the specialist will be excellent, for he is developing a better knowledge of the natural history of diseases, a more cautious view of the speeds of recovery, and a clearer understanding of the large gap that exists between “ fit for discharge ” and “ fit for work ”

SUPERLATIVE ASEPSIS

THERE are as many variations in sterile surgical techniques as in the allied field of religious ritual , and in both there is an ideal of ultimate purity, seldom attainable but serving as a goal towards which disciples may strive Professor GUDIN [1] of Rio de Janeiro seems to have approached the goal in his operating technique and when new theatres are being planned his ideas deserve consideration He recognises three phases in surgery the first, lasting centuries, characterised by ignorance of micro-organisms , the second, which began with LISTER, notable for partial control of bacterial action and the appearance of healing by first intention , and the third, which we are now approaching, the phase of total sterilisation, in which a new type of healing will be the rule—something that might be called Pasteurian cicatrisation Healing by first intention, as seen in an operation wound, he points out, is healing of a wound contaminated by the air of the theatre , there is an inflammatory reaction in which the healing response of the body quickly gets the upper hand That the air in the theatre carries infection under ordinary conditions can easily be demonstrated—gloves and instruments sterilised, covered with agar and exposed in the theatre quickly grow colonies of organisms, some of them pathogenic The air, as GUDIN shows, can only be sterilised if the walls and equipment are sterilised at the same time He does not despise air-conditioning plants and ultraviolet lamps as accessory aids, but he regards them as inadequate when used alone because they act solely on the air He has devised a “ total steriliser,” which, placed in the hermetically closed operating-theatre and controlled electrically from an adjoining room, sterilises the whole theatre and its contents The apparatus first liberates formaldehyde in an atmosphere saturated with moisture, and after this has done its work ammonia is released To remove the hexamine thus formed the air is pumped through a solution of tartaric acid, and the air-conditioning apparatus is put in operation The hexamine is soluble in water and any excess of ammonia combines with the tartaric acid That the air, walls and equipment of the theatre are thus rendered aseptic is shown by exposing agar plates after the total steriliser has been at work , they remain sterile

Only the surgeon and his team and the patient are allowed into this sterilised theatre Students watch operations through a glass panel let into the ceiling, and the ceiling is specially low to give them a good view The operating team reach the theatre through four previously sterilised anterooms—two for the preparation of the patient and two for the surgeons’ preliminaries Surgeons and patient discard all clothing before entering the sterile rooms and are dressed in sterile overalls made to cover the entire body like diving suits The surgeons’ hands are prepared by scrubbing with a succession of sterile brushes for 10 minutes The patient’s skin at the operation site is cleansed with benzene and then treated for at least 10 minutes with a freshly prepared 10% iodine tincture The anæsthetised patient is wheeled into the theatre on a mobile operating-table, to which instrument trays and discard bags are attached so that the whole unit can be removed to make room for the next patient The surgeons wear goggles as well as masks and gloves and do not speak while in the theatre , no-one with an upper respiratory infection is allowed in Sweating is prevented by careful air-conditioning

GUDIN’s precautions are aimed at excluding the three main sources of wound contamination in the theatre—the air, the hands of the surgeon and his assistants, and the patient’s own skin His sterilisation of the air seems bacteriologically irreproachable, but the method of using ultraviolet light as practised by DERYL HART [2] is simpler though not so comprehensive Much of this air-sterilisation should, however, be unnecessary if one could be certain of preventing contamination from the respiratory tracts of the theatre occupants and from the hair, clothing and skin of the operating team Efficient masking is a sine qua non, and changing of clothing and shoes should be an invariable rule Spectators must be screened off by glass, though the student will lose a lot by not hearing the surgeon’s comments , there is much to be said for a running commentary by someone other than the surgeon In one Canadian unit the surgeon wears a small sterilised microphone attached to his gown, through which he can broadcast to students or dictate to his secretary Goggles, as worn by GUDIN, shield the eyebrows, which commonly contain staphylococci And it is well to remind the junior nursing staff of the theatre to have their hair completely covered, the patient, too, especially when the operation is being done under local anæsthesia, often lies unmasked and uncapped The practice of bringing the patient into the theatre covered with blankets from the ward, teeming with streptococci, could be stopped now, without waiting for the days of super-sterility With simple care these sources of infection can readily be excluded, and RICE, WEED and RAIDT,[3] having made a thorough bacteriological study of the subject, conclude that "the bacterial content of the air in the operating-room may occasionally be a source of infection, but its importance has been grossly overemphasised" One of the most potent sources of wound infection is the surgeon's or assistant's hands via the pricked glove DEVENISH and MILES[4] have shown that some 15% of unpatched and 24% of patched gloves are found to be punctured after the operation, and they actually traced an epidemic arising from a surgeon's hands carrying *Staphylococcus aureus* HIRSHFELD[5] recalls that HARVEY CUSHING, who had an extremely low sepsis incidence in spite of his hands being exposed to unsterilised air during long operations, always wore heavy gloves The non-touch technique is an added but still not complete protection against these accidental punctures Unfortunately a multitude of brushes and repeated scrubbing for 10 minutes will not ensure complete sterility of the hands According to PRICE[6] there are two types of organisms on the skin—the transients and the residents Washing will get rid of the transients but the residents are more securely dug in As COLEBROOK[7] has shown, 5 minutes washing is usually ample, and more, especially in busy times, will severely damage the surgeon's skin He has also demonstrated that it is better to wash in a little water, say 3–4 pints, with plenty of soap, than under the running tap, for most of the pathogens commonly met with in surgical sepsis are readily killed by soap Cleaning the patient's skin as recommended by GUDIN is sound, but the fair-haired Englishman's skin will not tolerate 10% iodine COLEBROOK has in fact shown that 2% iodine in tincture or watery solution for 3 minutes is sufficient, and liquor chloroxylenolis (or antisepticus) of the NWF is just as efficient But all this care—the surgical fiddle-faddle, as CLIFFORD ALLBUTT called it—will come to nought if sterile technique is discarded at the subsequent wound dressings, and there are still too many surgeons who have not digested, even if they have read, the MRC memo on hospital wound-infection[8]

If any surgeon thinks his results are not capable of improvement in relation to infection, he will probably be disillusioned if he keeps records of postoperative wound reactions as well as of more serious infections The enthusiast for chemotherapy will remark that preoperative and postoperative sulphonamides will shield his patient from all hazards, but the happy day has not yet come when we may feel so sure of our power to immobilise invading bacteria that we can cheerfully let them in Chemotherapy must still be a reserve line of defence

MORE PÆDIATRIC PLANNING

SINCE the last reference to this subject in these columns[1] the word "pædiatrics" has been admitted to the columns of the *Times*[2] without a protest from Mr A P Herbert, and Prof L G Parsons has submitted a memorandum to the board of management of the Children's Hospital, Birmingham, on the improvement of teaching in pædiatrics in the University and for the provision of a pædiatric service for Birmingham and district To these notable events may be added the establishment of a chair of child health in the University of Durham to be filled by Dr J C Spence Industrial Newcastle thus follows the precedent of industrial Leeds where Dr C W Vining holds the chair of children's diseases Prof Parsons starts off with the important observation that pædiatrics is not a specialist subject but one which concerns the general study of children in health and disease and is not limited by one aspect of disease or by disease of one organ Prof G B Fleming has made the same point clear[3] For this reason, children's hospitals are not special hospitals, indeed they are more "general" hospitals for children than the so called general hospitals, some of which exclude diseases like pulmonary tuberculosis Thus any scheme which plans reorganisation of the hospital services along the lines of taking the special hospitals more directly into the orbit of the general hospitals must not assume that the children's hospital can be classed with (say) ophthalmic or gynæcological hospital Pædiatric planning indeed starts with the children's hospital as the centre of activities for the care of the child in health as well as sickness

London is planning on these lines also, according to a letter[4] from Lord Southwood, chairman of the Hospital for Sick Children, in which he indicates that he is also chairman of a "committee for the coordination of the medical services for the children of London" which appears to have started with the hospital services as the essential feature of the future of pædiatrics Both in Professor Parsons's memo and in the *Times* article it is clearly shown how this may be brought about The pædiatric surgeon (and indeed the pædiatric physician) takes little or no part in public preventive or social medicine, while medical officers in the child welfare and school medical services are often overburdened with administrative duties to the detriment of their clinical work Both groups have their contribution to make to the study of the child in health and disease and yet they are apt to be suspicious of one another In Birmingham it is suggested that the Children's Hospital should be closely linked with the pædiatric services of the city and region The whole of these services would then be available for teaching purposes and their medical officers would receive postgraduate instruction at the hospital and be eligible there for posts as clinical assistants Contrariwise members of the hospital staff would be available for work at welfare centres Professor Parsons would also like to see an infant welfare centre developed at the hospital, a home for cardiac cripples, a "preventorium" for children with the primary tuberculosis complex, an extended almoner's department to form a real social service department, as well as education facilities and a development of occupational therapy An interesting suggestion is for a "humanity" department where telephone and personal inquiries can be answered in kind and simple language Many other suggestions appear in the Birmingham scheme which have a wide application

Following the primary need of a comprehensive service, and complementary to it is the question of the education of the medical student. The modern student, the *Times* hopefully remarks, is interested in children, but with only the possibility of a question in his final examination, and so much else to make sure of, he takes the chance of getting qualified without any real knowledge of the child in health or sickness. In Canada and America pædiatrics has its place in the finals alongside medicine, surgery and midwifery. To teach pædiatrics—not merely diseases of children—in its full curative and preventive aspects implies the coöperation of children's hospitals and public health work and efficient training of the whole personnel from hospital nurses, health visitors and school nurses, right down the scale to the family nanny, if such a worthy person is still to be found in the post-war world. Indeed training of workers in the pædiatric field should be the first task of any new national service for children's health. Prof Chas McNeil writing more particularly of the newborn baby has stated bluntly[5] that in this respect the state of preventive pædiatrics in this country is second-rate; but he is convinced, as was quoted in these columns recently, that this can be put right by teaching and training. At the moment organised medicine is in danger of dropping behind public opinion in this matter. Of course pædiatrics is a major subject. Its future developments have a national importance. The blue prints for Birmingham, London or Durham must be on view for all to see.

THE THOMAS SPLINT

Hugh Owen Thomas would still have been a major contributor to orthopædic surgery if he had done no more than design the knee-splint which bears his name. Diggle on another page reminds us, if reminder were necessary, of the efficiency with which fractures of the femur can be treated in it using skin-traction by strapping. As he points out, the main criterion of success in estimating the results of treatment is not the amount of shortening—provided this does not exceed three quarters of an inch, within which it is easily compensated for—but the final range of movement in the knee. If the knee cannot be bent to a right angle a year after the fracture the treatment must be regarded as having failed, for this range should have been regained within the first 9 months. At the end of the period of traction the patient treated with a transfixion pin and the knee flexed may have an impressive range of motion, while at the same stage after skin-traction on a Thomas-splint the knee may be almost completely stiff, yet it is a common experience for recovery in the latter case to outstrip the former rapidly and to reach full, or nearly full, movement while the other may never do so. Because the efficient use of the Thomas calls for painstaking and continuous attention to the numerous details of slinging, support and extension, there has been in recent years an increase in the popularity of the Braun frame used with skeletal traction as a simple and less laborious mode of treatment in which the patient can be left to his own devices after the primary reduction. Excellent results can thus be achieved, but, apart from the avoidable dangers of over-extension and infection of the pin-track, the frame is not a splint and there is relatively little control of the upper fragment, especially when the fracture is in the upper shaft. Armstrong[6] has pointed out its inefficiency in dealing with fractures of the upper third, advocating a return to the Thomas for this injury. Diggle's article is timely as a vindication of old-established method now when fractures of the femur have to be treated in places where the Thomas splint and the simple apparatus that goes with it is the only means available. It is important therefore that the supply of splints to each centre should embrace an adequate range of sizes with gradual increases of 2 inches between the extremes, and that splints should be the right length. Otherwise it may be impossible to fit the splint to the patient's thigh, to add a windlass for fixed traction and to transport patients comfortably, and hospital splint rooms may be cluttered up with a host of useless, because ill-designed and hurriedly made, splints—a situation familiar in the early days of the present war.

LOSS OF LIFE IN TWO WARS

Greenwood[1] has shown that loss of life in the British armed forces in the wars of 1794–1815 and 1914–18, in relation to the male population, was about the same. If account is taken of civilian losses of life directly or indirectly due to the war, which were important in 1914–18 and negligible in 1794–1815, the number of deaths was relatively greater in 1914–18. Greenwood's comparison of the deaths in the two wars is summarised in the following table compiled by Isserlis. In the last column the totals for 1914–18 are divided by 2·5, the ratio of the male populations of the United Kingdom in 1911 to that in 1811.

1794–1815		1914–18		
		As recorded		After division by 2·5
Navy—		Navy and Merchant Marine	48 000	
By enemy action	6 663	Land Forces	724 000	
			772 000	
By marine risk less peace totals	11 905	Deduct peace totals	65 000	
By disease &c less peace totals	44 662		707,000	
	63 230	Deduct 22% for Dominions	156,000	
Army (similarly calculated)	143 808		551,000	220 000
	207 038	Sea passengers and civilians killed in raids	8,389	
Civilians— By enemy action i e, in privateers	?	Underestimated say	4,111	5 000
			12 500	225,000
By excess of civilian mortality	Nil	Excess civilian mortality not including influenza	187 500	75 000
Say	210 000	Say		300,000
Loss of births	Nil	Loss of births say 500 000 to 700,000		240,000
	210 000			540 000

Detailed and reliable figures are not available for the period 1794–1815. Official publications relating to the Navy were confined to numbers of men voted, and returns of killed and wounded. The War Office compiled more statistics but they were defective and incomplete. The figures shown in the table for 1794–1815 are chiefly the estimates of W B Hodge.[2] The comparatively small number of deaths caused by direct enemy action and the large number due to disease and accidents of war is remarkable. Hodge made the ratio of non-battle to battle casualties 8 to 1. In 1914–18 (land forces) it was 1 to 5·3. Hodge's method of obtaining the number of additional deaths in the Navy arising from disease and ordinary accidents caused by the war (the figure 44,662 in the table) is interesting. He estimated the average number of men serving annually in ships at sea as 110 180. He then calculated that these men were subject to an additional risk of death through disease or accident owing to the war, at the rate of 16 per 1000. This in 20·45 years of war gave 36,051 as the number of additional deaths caused by disease or accident as a result of the war. But allowance had also to be made for the fact that some 70,000 of the 110,180 men serving were civilians who were subject to an increased risk of death while serving as sailors, quite apart from the war Hodge adds the difference between the expected deaths as civilians and the expected naval deaths to his 36,051, giving a total of 44,662 Greenwood's net figure of casualties in the armed forces in the 1914–18 war is obtained in a similar way, by deducting from the total number of deaths the estimated number of civilian deaths He emphasises that his comparison is made from a purely arithmetical point of view "Economically and psychologically a bill which must be paid within four years is more onerous than one which is discharged by twenty annual payments" Apart from the different length of the two wars, there were two heavy costs in terms of human life in the 1914–18 war which did not apply in that of 1794–1815 Losses of life due to direct enemy action against the civilian population or disease consequent on a lower standard of living were negligible in the war of 1794–1815 There is good evidence that the general health of the people improved during the war, partly due to a higher level of real wages The case was far different in 1914–18, when 6330 sea passengers were drowned and 2059 civilians were killed in air-raids or coastal bombardment In addition the death rate increased Vedel-Petersen[3] estimated excess civilian mortality in England and Wales during 1914–18 at 281,000 Of these more than 130,000 belonged to the pandemic of influenza Opinion differs on what proportion of these excess deaths, particularly those caused by influenza, was due to the war A further factor in 1914–18 was the loss of births Sir Bernard Mallet estimated the shortage at 500,000–700,000 In 1794–1815 there is no reason to suppose that the war affected the birth rate at all, since the overseas armies were small It is interesting to contrast civilian and service death-rates in the two wars In 1794–1815 the annual deaths among serving men, additional to an estimated civilian rate of 10 per 1000, were at the rate of 32 8 per 1000 In 1914–18 the civilian rate was 4 8 per 1000 per annum and the annual deaths additional to this in the armed forces were at the rate of 52 3 per 1000

POSITIVE CONVALESCENCE

TODAY we must all help to make the wheels go round and we cannot afford to carry passengers, so economy supports humanity in the demand that everyone who falls ill or is injured should be completely restored as quick as possible The EMS rehabilitation centres, where groups of patients with similar lesions are collected and treated together, give good results and are sparing of equipment and trained personnel But at the congress of the Chartered Society of Massage and Medical Gymnastics on Sept 18 both Prof John Ryle, who gave the opening address, and Prof F R Fraser warned these trusted handmaidens of medicine against the dangers of overspecialisation Ryle told the masseuses that they were the mediators between disease and health , whatever happened we should need them badly For the future, he thought, they would need a better appreciation of the purpose of their work, closer cooperation with other branches of the medical and health services, and a broader training in their craft They must learn to see the patient not only in terms of his injury but as an individual against the background of the community Both Ryle and Fraser were sure that simple improvised apparatus could give better results than expensive and stereotyped routine (it was Opie who, when asked with what he mixed his paints, replied "with brains, Sir") and Fraser, while giving the mass methods of war time their due, cast a nostalgic glance back to the old days when each patient was a problem whose rehabilitation must be provided within the limits imposed by his habits and environment Today the work of the masseuse, the physical training instructor and the occupational therapist tend to be limited each to its own sphere But tomorrow we may well want a paragon who will combine the skill of all three with the insight of the psychologist and the zeal of the social worker, for in Ryle's words, we shall not only be mending broken men but a broken world Ministers of the Crown are vying with each other in their adulation of toughness, fitness and physical development, but as Lord Horder, president of the society stressed, it would be up to us to keep the ministers to these ideals when the hurly burly is over

MEDICAL JUDGE

HIS HONOUR DIGBY COTES-PREEDY, KC, was a truant from medicine After being house physician at St George's and editor of the hospital journal, he read for the bar and was called by the Inner Temple in 1904 But he could not and would not forgo his medical background, and whether as advocate in the divorce court or as judge on circuit he had the informed and sympathetic outlook of the biologist on the events of human life He made a special study of the law relating to hospital authorities and was a lively member of the departmental committee on coroners "Competent and popular" certainly, in the words of the *Times*, and more than that for he had the double gift of interpreting medicine to the legal mind and almost of justifying the law to the medical mind He will be missed both by bar and bench

UNSIGNED COMMENT

ON another page Professor Fisher writes with feeling about the abuses of anonymity, taking as his text an unsigned review in our own columns and comparing it with a signed review of the same book in another weekly journal From his quotations it appears that the unsigned review was the more critical of the two and he thinks that readers of THE LANCET would have been better served by being told the identity of the reviewer, so that they could judge for themselves the value of his opinion Professor Fisher suggests that the reviewer who comes out into the open is less likely to say things which he cannot substantiate—putting it more baldly, to talk through his hat If that impression were true Professor Fisher would have proved his case, and it would follow that all expressions of critical judgment, whether in reviews, leading articles or annotations, should be attributed to their multiple sources, which would be impracticable if not absurd But is it true? Dr A writes a monograph on a new subject or develops a theory to explain some old observations and Dr B gives his opinion on it in a signed review It will be plain sailing, though no mean task, to set out briefly the gist or message of A's work, and praise or minor criticism will present no difficulty But if he has reason for major criticism B may give offence or involve himself in interminable argument by writing frankly, so he may well say less than he thinks Dr C, on the other hand, when he drafts an unsigned review, will tell the editor all that is in his heart and look to him to put it in proper form The editor will then exercise his function as a clearing house of informed opinion by bringing C's comment into line with other views There is little scope here for the exploitation of anonymity and a rather long experience suggests that author and reader are gainers although the reviewer may sometimes suffer

MR SHEFFIELD A NEAVE, DSc, CMG, is to fill Dr Julian Huxley's place at the Zoological Society of London until the spring annual meeting He is believed to know most of the 225,000 genera, large and small, of the animal kingdom, but quite certainly has an intensive knowledge of the insects harmful to human progress, especially the tsetse fly As travelling pathologist and naturalist he follows in the footsteps of his father, whose name he bears, a naturalist who took up medicine late in life and had the naturalist's eye for small variations from the normal

HONG-KONG ON THE EVE

P B WILKINSON, M B LOND, M R C P
ATE MEDICAL OFFICER IN THE COLONIAL SERVICE AT HONG KONG

HONG-KONG proper is a small island 36 sq miles in area lying off the south coast of Kwantung province The whole colony embraced many other islands and a mall area of the mainland which stretches inwards from the Kowloon peninsula for about 20 miles The island s just within the northern tropic and has a subtropical climate that is to say from May to October when the south-west monsoon is blowing, the maximum day temperature averages 87° F and the relative humidity is also high, from November to May, the so-called winter period when the north-east monsoon is blowing, the maximum day temperature averages 66° F and the weather is agreeable The annual rainfall is about 70 in and most of this falls during the hot season

When the English took Hong-Kong from China in 1841 after the victorious conclusion of the Opium War, the island was a barren, inhospitable and uninhabited rock Although it was occasionally visited by pirates it was for the most part avoided by the Chinese of the adjacent mainland because malaria was rife A hundred years of English occupation have done a little to improve the island, which is now habitable It is still comparatively treeless and flowerless, and vigorous attempts at afforestation have only succeeded in making it look like the dream of a third-rate horticulturist with a passion for conifers A gigantic city, Victoria, has sprung up on the landward or northern coast of the island and it is confronted by a slightly smaller city, Kowloon, on the mainland It may be said with truth of the English, that they carry two things all over the world—their beer and their architectural vulgarity Both abound in these two cities, but Victoria takes precedence over Kowloon for the vast extent and unparalleled squalor of its slums

These two cities have grown up because Hong-Kong, by virtue of its position at the mouth of the Pearl River offers easy access to Canton, the capital of South China The enormous entrepôt traffic which developed during the last century made Hong-Kong one of the biggest and wealthiest ports in the world Its population in 1937 was approximately 800,000 By the end of 1942 that figure had risen to 1 750,000, because of the unceasing influx of refugees and other victims of Japan's war of aggression on China Before the outbreak of the Sino-Japanese war in 1937 it was estimated that 10 000 ships cleared the port every year When one remembers that in addition to this immense sea-borne traffic there was a daily inflow and outflow of 8000–12,000 from the mainland to the island and back, it is easy to realise how vulnerable the island was to those epidemic diseases which prevail in the Far East During the last few years the development of air-lines increased this danger, and the story of medicine in Hong-Kong during the last few years was early the story of the efforts made to combat the threats to the island from air-borne, sea-borne and land-borne diseases

Air-lines running to and from the colony were few, and the passengers were examined on arrival The one great danger which faced health officers responsible for the control of air-borne passengers was yellow fever, but stringent precautions were taken by all countries interested which successfully prevented the importation of this disease Sea-borne traffic, when one is dealing with ocean-going ships alone, was comparatively easy to cope with since the introduction of radio-pratique in 1938, though I have seen cases both of cholera and typhus which arrived in Hong-Kong by sea But the innumerable junks and sampans which plied between the island and the mainland, and the coastal ports, presented an insoluble problem

The risks from land-borne traffic were perhaps gravest of all Hong-Kong has been a free port since the English took it in 1841, this means that no restriction of any sort was imposed on immigrants from the mainland of China This state of affairs adds intolerably to the burden of health officers, and unsuccessful attempts were made to exercise some control over mass immigration For political reasons it was obviously not expedient to introduce any drastic restrictive measures during the last four years against people who were soon to be our allies, and those measures which were introduced were speedily nullified by the intelligence and ingenuity of the Chinese For example, it was suggested that a poll-tax of ten Hong-Kong dollars be imposed on each immigrant, our twenty-mile land frontier was instantly manned by smiling money-lenders brandishing the necessary notes and recovering them at a handsome profit when the frontier formalities had been complied with During the four years 1937–41 immigrants and refugees poured into the colony in an unceasing stream and the daily tidal population also increased considerably These factors, coupled with a steady fall in the standard of living and housing conditions greatly increased the incidence of epidemic disease and deficiency diseases in the colony, and the mortality from beriberi and pellagra, for instance rose to unprecedented heights during the last two years

THE PRODUCTION OF ANTIBODIES

OUR knowledge of the processes by which antibodies are formed is very incomplete It is not even known for certain what cells in the body are responsible for the production of antibodies Current theories fail to explain certain characteristics of antibody production Antibody activity is generally accepted as a function of modified serum globulin molecules, and the essential problems are to determine how normal serum globulin is produced and how antigens introduced into the body can influence the cells concerned so that specifically modified globulin is formed An alternative hypothesis of antibody production has been suggested by Burnet and his colleagues at the Walter and Eliza Hall Institute, Melbourne[1] Recent work supports their conclusion that antibodies correspond physically to the globulins normally present in the same animal species and the type of globulin utilised varies with the animal species and the type of antigen concerned For example, specific pneumococcal antibody in the rabbit and man is associated with globulin molecules of normal size, while this antibody in the horse is associated with heavy globulin molecules such as are present in only small amounts in normal horse serum, diphtheria antitoxin prepared in the horse, however, is found in pseudoglobulin molecules not different in molecular weight from normal The Melbourne workers suggest that the plasma proteins probably serve as a mobile store of protein, and the disappearance of antibody from the blood of an immunised animal may be due to its destruction and utilisation for protein reconstruction Of the globulin increase during immunisation not more than 30% is accounted for by antibody and it seems likely that a considerable proportion of normal serum globulin is prepared by the cells responsible for antibody production

Certain deductions about the mode of formation of antibody can be made by considering the rise and fall of antibody in the blood after first and subsequent injections of antigen into animals In illustrative experiments with different kinds of antigen done in Melbourne the difference between the primary and secondary antibody response was greater after injections of toxoid than after injections of bacteria or bacteriophage, while the secondary response was not demonstrable in the type of experiment carried out with the rickettsia of Q fever or herpes virus With most of the antigens, however, a logarithmic increase in antibody could be shown to occur under suitable conditions over a short period This logarithmic increase can be accounted for by the hypothesis that there results, from second injections of antigen, proliferation of the antibody-producing mechanism so that over a short period a progressively increasing number of units come into play, these may be cells or subcellular units The later phase of the antibody response varies with different antigens When certain antibodies are transferred passively to an animal the rate of fall is rapid and logarithmic but this does not occur after active immunisation when the fall becomes slower with time This is probably due to continued production of antibody at a diminishing rate and a steady removal of antibody at a rate proportional to its concentration It is suggested that the different types of antibody response evoked by different antigens in the same animal species may be related to differences in the groups of cells concerned with the antibody formation.

[1] The Production of Antibodies A Review and a Theoretical Discussion F M Burnet, MD Melb, FRS With the collaboration of Mavis Freeman, BSc Melb A V Jackson MB Melb and Dora Lush, MSc Melb Melbourne Macmillan Pp 76 8*s* 6*d*

Although direct proof is difficult to obtain it has generally been accepted that the reticulo-endothelial cells in the liver, spleen and bone-marrow are mainly concerned with antibody formation following intravenous injection of antigen. The evidence on this point has not been reviewed by Burnet but he discusses the part played by the germinal centres of the lymph-glands and spleen and gives details of hitherto unpublished experiments. After injection of virus, phage or bacteria antibody was demonstrated in the lymph-nodes draining the site of injection before, or in greater amount than, in the blood. The experiments with staphylococcus toxoid were not so conclusive, perhaps owing to the diffusibility of this antigen. Experiments on local production of antibody at the injection site were negative but the findings of others have been positive. The general conclusion drawn is that antibody is produced by those phagocytic cells of the reticulo-endothelial system which ingest the antigen. Which group is actually concerned is determined by the site of infection or inoculation and subsequent spread of antigen in the body. The available evidence indicates that antigens are destroyed soon after being taken up by the reticulo-endothelial system but antibody production goes on. Although attacks of measles and yellow fever are followed by life-long immunity there is no evidence that immune persons are virus carriers in these two diseases; the long-lasting immunity must be accepted as something induced by the infection but maintained by the body after all the virus has been destroyed. Burnet suggests that the antibody concerned with allergic states is produced by tissue histiocytes near the site of infection or inoculation and differs in several respects from that produced by the reticulo-endothelial cells of the major antibody-producing organs.

Any acceptable hypothesis on the mode of formation of antibodies must take account of the immunological facts outlined above. The Haurowitz-Mudd theory of antibody synthesis in direct spatial contact with the antigen is inadmissible, if the evidence is accepted that antibody production can continue after destruction of the antigen. The central feature of the hypothesis put forward by Burnet is the use of Bergmann and Niemann's conception of the dual proteolytic and protein synthetic activity of intracellular proteinases, but it goes further. Whereas according to Bergmann and Niemann, protein is synthesised by intracellular enzymes which work up the available material until a protein exists which is stable in presence of the enzyme, Burnet suggests that the living protein molecules within the cell are themselves possessed of proteinase activity and continually produce replicas of themselves. Such proteins as those in the blood and in glandular secretions may be regarded as partial replicas of the living protein unit responsible for their production.

Antibody globulin is probably synthesised within cells of the reticulo-endothelial system by certain proteinase units of the cells. These units are modified by contact with foreign antigens and liberate partial replicas of themselves into the blood and lymph. This modification is not to be regarded as resulting from a synthesis of a new unit in spatial contact with the antigen but rather by a process analogous to the production of adaptive enzymes of bacteria. Certain bacteria, by culture for some time in the presence of a sugar not normally fermented, will acquire the property of fermenting it; contact with the sugar can impress on a bacterial enzyme a new specific power of acting on the new substrate. Similar changes in some bacterial enzymes responsible for protein synthesis have been demonstrated and in certain instances the changes are inherited. In the light of this work on adaptive enzymes of bacteria it is suggested that the primary modification of the proteinase within the antibody-producing cells is such a reorientation of its atomic structure as is necessary to allow its effective hydrolytic activity on the foreign antigen. The modified proteinase retains its modification during subsequent production of complete or partial replicas. In the absence of further contact with the antigen, however, successive new formation of replicas of the modified proteinase will probably gradually eliminate the impression and ultimately normal globulin will be produced. In the intermediate stages, low grade antibody which unites less readily with the antigen will be formed. Further contact with the same antigen will, on the other hand, intensify the impression and an opportunity will be presented for modification of other aspects of the proteinase to occur. This hypothesis explains the observed difference between antibody produced in response to a primary stimulus and that obtained at the end of a long series of injections.

The hypothesis suggested by Burnet and his colleagues has some features in common with Ehrlich's theory. The intracellular proteinase would correspond to Ehrlich's cell receptors, which by contact with antigen became diverted from their normal function and were produced in excess. Ehrlich's view that superfluous receptors shed into the blood-stream constituted the specific antibody is not very different from Burnet's conception of antibody as the partial replicas of modified intracellular proteinase. We are still ingorant of the biochemical processes involved in the formation of these intracellular proteinases and further knowledge may have to await the development of new methods. Although antibody formation by tissues cultivated in vitro has been studied by a few workers refinements in the technique of tissue culture and methods for the cultivation of single cell types might provide a means of investigating certain questions which are still unanswered. The chief advantage of the new hypothesis over the orthodox theory of antibody production is its power to interpret the qualitative changes in antibody which accompany prolonged immunisation. It is compatible with most of the established data and should prove stimulating to workers in the field of immunology.

A W D.

A PLACE FOR THE ASSISTANT NURSE

THE reconstruction committee of the Royal College of Nursing, under the chairmanship of Lord Horder, has come at once to the point over a fundamental question in nursing today. Should the assistant nurse become a recognised part of the nursing service? The Alness Committee, it will be remembered, in its findings for Scotland, was against giving her official status; but since then the Civil Nursing Reserve in Scotland has recognised the grade officially. The Athlone Committee considered that assistant nurses should be controlled and their position regularised; and the Horder Committee, in the first section of their report,[1] are firmly of the same opinion. Assistant nurses have been defined as women who, being neither state registered nor in training for the state register, undertake nursing for a livelihood. The committee estimate the number of assistant nurses working in Great Britain at "many thousands" even though they have deliberately left out of consideration at this stage those nurses holding the certificate of the Royal Medico-Psychological Association. It is fair to say that the nursing service of the country at the present time could not be maintained without the aid of assistant nurses, and Lord Horder, looking at things from the national rather than the sectional angle, in his foreword described their position as pivotal. The aim of all bodies interested in nursing today is to ensure a complete service, preventive and curative for everybody in the country. In such a service the assistant nurse can take a useful part, the committee believe, not only in caring for the chronic sick—in which she is already prominent—but in dental clinics, factories and other routine services, attached to private nursing cooperations, associations or nurse supply agencies, working independently or employed in hospitals and nursing-homes—always provided her work is controlled and supervised.

State-registered nurses may be forgiven if they do not at once take kindly to the suggestion that a lower grade of nurse should enter all the spheres where fully qualified women are already working. Industrial nurses have already protested in the press against the idea that an assistant nurse would be fitted to deal with acute injuries and fractures in factories. But in a large factory assistant nurses may well form a useful team working under a state-registered nurse, especially in departments (packing or sorting) where the liability to gross injury was slight. Indeed, the Ministry of Labour and National Service has recently suggested (Form 327) that, provided a fully trained nurse is in charge, additional assistance can be given by "one or more less well-qualified but suitably trained persons" Opposition to a second grade also comes from state-registered nurses in private practice who naturally suffer from unqualified competitors and who would suffer still more, presumably if these competitors were given official standing Others oppose recognition of the assistant nurse because they know little, perhaps of the valuable part she plays in the care of the chronic sick The fact remains that since the outbreak of war the demand for nurses has increased, and the sources of supply—never adequate, even in peace-time—have shrunk It has been suggested that the standard of the state examinations should be lowered so as to bring them within range of the capacity of those who are now assistant nurses, the committee are against any such drastic reduction of standards considering that the institution of simple practical tests for the assistant nurse would be a much better plan

---

[1] Obtainable from the secretary, Royal College of Nursing, 1, Henrietta Street, W 1. 1s, post free 1s 2d.

Assistant nurses have come into being in a haphazard manner at present a student nurse can abandon her training to join a cooperation or agency as an assistant nurse and is then in a position to return to her own training school in that capacity at a far higher rate of salary than her colleagues True she no longer has the chance of qualifying and gaining promotion, and she will probably be limited to routine tasks and a fixed salary for the rest of her life but this may suit her ambitions and her capacity The committee recommend that assistant nurses should continue to be known as such and that they should be enrolled under the General Nursing Council Nursing then should be a closed profession practised—except for student nurses, and assistant nurses under instruction—only by state-registered nurses and enrolled assistant nurses Instruction would last two years and be preceded by a period in a preliminary training centre The first year would be spent in a hospital for the chronic sick, in the second year the assistant nurse would have experience in fever mental or tuberculosis hospitals, and would return to nurse the chronic sick while attending classes in cookery and occupational therapy The examination recommended is a simple practical oral test lasting at least an hour The qualified assistant nurse would wear a distinctive attractive and serviceable uniform, and employing authorities throughout the country would be encouraged to adopt it for those in their service The General Nursing Council would be responsible for inspecting approved centres of instruction The committee are not in favour of student and assistant nurses being taught together It is suggested that during the period of preliminary training the assistant nurse should get 10s weekly, and during the rest of her training should be paid at the rates laid down for the first and second year student nurse After enrolment she should get, in hospital, £70 yearly, rising by annual increments of £5 to £95 (that is, within £5 of the starting salary of a state-registered staff nurse) To encourage her to stay in one post long-term service should be rewarded by five-yearly increments of £5 Superannuation would be obligatory In private practice it is recommended that she should receive £2 10s a week, with board, lodging, travelling and laundry

The committee deal clearly with the misconception that the establishment of two grades of nurses would mean that the poorer patients would only get the services of the lower grade of nurse They stipulate that the patient's physical condition would decide what grade of nurse attended him Cooperative and nurse-supply agencies would be required to send to the applicant for nursing service within 24 hours, a form setting out the professional status of the nurse sent out, and the nurse herself would be required to carry a card showing whether she was on the register or on the roll of assistant nurses

Legislation would be necessary of course, to put these suggestions on the statute book, and the committee recommend measures to prevent hardship to practising assistant nurses if such an act should become law They would have to provide evidence of the justice of their claims and to apply within a year for inclusion on the roll They would have to be at least 20 years of age, and would have to show that they had had two years instruction in an approved hospital and that they were of suitable character All others would have to take the prescribed course of instruction

MEDICINE AND THE LAW

Professional Liabilities in War-time

ADDRESSING the annual meeting of the Medical Defence Union last week, Dr James Fenton the president, said that the war has not, as some have thought, diminished medical litigation And he went on to draw attention to the possible liabilities of a medical practitioner when following his profession as a member of H.M. Forces If negligence be attributed to him he must not expect the state or the military authorities to accept responsibility It is true that, if the driver of an Army lorry or a Post Office van runs over a pedestrian in circumstances resulting in a claim for damages by the injured person, the Treasury Solicitor usually steps up unobtrusively behind the defendant and undertakes the defence as well as finding the money which may be awarded as compensation The plaintiff in such cases has a somewhat nugatory legal right to sue the driver personally and no right at all to sue the Crown which is his employer What the Treasury Solicitor may do is done as an act of grace, it by no means follows that he will undertake the defence of officers of a medical unit if they are sued for damages for negligence, the view may be taken that the doctor can reasonably afford to pay for his own litigation and to satisfy claims based on allegations of want of professional skill and care Nor can the Treasury Solicitor be expected in any event to bring to the aid of a defendant doctor the same specialised skill as the lawyers who conduct litigation on behalf of the medical defence societies As the societies are assisting medical officers on charges before courts-martial as well as in the common-law courts the importance of continuing membership of a trustworthy defence organisation speaks for itself

The task of the societies indeed grows no less in war-time The doctor who remains in non-military practice may find himself short-handed and overworked, his partner may be absent on service and assistance may be difficult to obtain or inexperienced If the practitioner finds himself hard pressed and hurried, that is just the time when those careful records are omitted or those certificates are less exactly worded which involve the risk or threat of distracting and expensive proceedings A medical attendant, intent on doing his best for his patient, cannot always be taking every precaution for his potential justification in the contingency of his appearance as a defendant in court Medical practice conducted with one eye on a prospective judge and jury is by no means necessarily in the interests of the patient, and when he is hard pressed the conscientious doctor will think of his patient's safety rather than his own

SUBDURAL HÆMATOMA

ACCORDING to D Furtado there are few intracranial lesions as interesting to so many branches of medicine and surgery as subdural hæmatoma (*Amatus Lusitanus* 1942, 1, 165) The lesion may be defined as a collection of blood more or less organised, beneath and adherent to the dura mater Its evolution may be chronic or subacute, rarely acute, and its origin traumatic or spontaneous Traumatic cases comprise some 60% of the total, the trauma may have been comparatively slight, and may have been followed by a long or short latent period The non-traumatic form may complicate any acute infective illness (pneumonia scarlet fever &c) and is probably an inflammatory lesion—a form of infective hæmorrhagic pachymeningitis The symptomatology is extremely variable, but the three cardinal symptoms are headache, psychical disturbances and eventual onset of coma The headache is often localised to the area of the hæmatoma, and the skull here may be tender on percussion Psychical disturbances are observed in about 50% of the patients In making a diagnosis a ventriculogram or arteriogram may be of great service The treatment is essentially surgical analysis of the available figures showing that without operation the outlook is black, while with operation 80% of cures may be expected

In England Now

A Running Commentary by Peripatetic Correspondents

As a foundation member I have probably abused the EMS as much as anyone but I am still a member of it and have now arrived at the stage when I am prepared to admit that it has not turned out too badly But there are still features of it to which I object Why, for instance, should I have to sign an elaborate form every month, certifying this that and the other, before I receive my salary ? No private institution to my knowledge has such a low opinion of its employees, and even I hate to draw the conclusion that the standards of honesty of the civil service are such that these forms are necessary Perhaps the boot is on the other foot and it is we temporary civil servants who are under suspicion, our permanent colleagues not being quite certain whether we can ever attain to those laudable ideals which have for so long characterised a Service which by virtue, &c , &c A much less personal grouse is the timidity with which the Ministry has run the EMS Why must we have this roundabout technique of the Ministry refusing actually to run a hospital and insisting that the organisation shall be in the hands of a local authority, the Ministry keeping well in the background and surreptitiously slipping an occasional cheque into the pocket of the local authority just to cover expenses ? Is there any reason why we (i e , the EMS) should be treated as a bastard whose father means well but must be oh so careful lest its parentage be recognised ? Surely the shibboleth of "state medicine" no longer carries any fears, and would this not have been a magnificent opportunity for the Ministry to show just how well it could organise and run a hospital service (overlooking for the moment its origin on the principle that bygones should be bygones)? Or would it not have been an excellent chance to gain invaluable first-hand experience of what running a hospital service really means ?

As far as I know my standard of work, my enthusiasm for my profession, my zeal for my patients have not deteriorated since I became a "civil servant" I am not aware that I watch the clock lest I should arrive a minute before time or leave a moment after time I do not recall ever refusing a night call because I had already completed my statutory hours of work for the week It has never come to my knowledge that my patients have been deprived of any drug or preparation because the "State" considered it a luxury Granted that the nursing is not what it might be but all comparisons are invidious, especially when one has always worked in teaching hospitals, and considering the present chaotic position of the nursing profession, with its acute shortage of recruits, our nursing attains quite a reasonable standard However, I may have been lucky in my experiences I work in a London sector where the sector officer is a personal friend, and, like many of my colleagues belongs to my own teaching hospital My house-officers are old students of mine and I still retain close connexions with my old hospital The result is that while officially we may be civil servants we still work according to the old traditions

* * *

A request to have finger prints taken usually implies a clash with the forces of law and order, but it was carefully explained that it was now customary to submit a set before travelling in the Western Hemisphere In the room was a figure similar to the one mounting guard over the presents at prewar weddings, so it was fairly evident who was to take them This mountain of flesh was kind enough to say that obviously I had not undergone the experience before I wish we could meet again, because in the course of entering and leaving 29 different countries in thirteen weeks, I have since acquired considerable skill in the technique , I might even give him a few tips A curious sidelight on travel nowadays is that the better one's credentials the more solemn the formalities, whereas the wicked seem to flourish despite irregularities However, their end, when it does come, is inclined to be abrupt

The bus to the airport was quickly loaded and on its way, through the dark and often damaged streets It was obvious directly the gate control had been passed that no latitude was allowed to individual travellers On alighting our little knot was led into a small room by a sergeant of the Security Police where embarkation cards were filled up, and the customs officers and censors did their stuff Then there were interviews for personal questioning with the Security Police and emigration authorities, to whom we were submitted one at a time in a side-room , what was my profession, did I have any special branch, was my journey abroad in connexion with this, and so on All these formalities completed passengers were taken into a pleasantly furnished waiting-room with a fire and offered tea and biscuits, which were welcome, for it was nearly 9 A M and breakfast seemed a long time ago It was now possible to observe the travellers in more detail The oldest was a grey haired Canadian who was acting as one of Roosevelt's "dollar a-year" men and had repeatedly made the journey by one route or another between England and America

To anyone like myself who had never flown before, the whole set-up of the preliminary arrangements, efficient though they were, detracted from the thing itself We were led rapidly to the awaiting Douglas machine, seated inside much as if it were the village 'bus, and in fact the number and arrangement of the seats, twelve in all were similar but for the greater leg room and the soft upholstery The blacked-out windows of the plane prevented any orientation or observation apart from the altimeter on the forward bulkhead which separated the passenger accommodation from the wireless gear and control cabin A member of the ground staff warned all passengers that a descent would be made in about thirty-five minutes , with that the outside door was shut and off we went The take-off was much as anticipated but the runway was so smooth that there was not the sudden sensation of being airborne as described in the books Once the machine had settled down on her course, rather like Jemima Puddleduck the engines were noisy but this was not so trying as the vibration experienced if one leaned back too firmly in the seat Subsequent journeys in numerous planes suggested that this matter of vibration is an idiosyncrasy of certain machine much as in ships

In due course we descended at an aerodrome for fuel to take us on the hop across the sea It was a typical Service aerodrome, though a special waiting room had been set aside for civilian passengers from which the ordinary events of the day could be watched during the wait The single line of railway alongside produced one thing of interest—a tank engine which despite its army paint could not hide its Stratford origin When one thinks of the duties these Holden engines, despite their age, still do on their home tracks, it probably accounts for their popularity in a second war

At this take-off everyone felt we were now really getting down to the day's work , it was already 10 30 After about twenty minutes' flying the blackout was removed, and there we were 3000 feet up in brilliant sunshine above the clouds The clouds completely obscured any view of the sea, but from time to time in the afternoon gaps allowed us a glimpse There were no ships about or signs of life till the coast of Portugal was sighted Luncheon appeared at 1 P M , served by the radio operator It consisted of a well-made green-pea soup, cold ham with bread and green salad followed by coffee It says a lot for the steadiness of the plane that it was possible to fill the soup plates completely At last we reached Cintra airport, 27 kilometres from Lisbon, and made a good landing on an aerodrome, much churned up because there was no proper runway for heavy planes We finally came to rest alongside a German plane, a JU 58, and an Italian plane, on both of which mechanics of characteristic faces were working It seemed strange that they were still tolerated in Europe Evidently the Portuguese and other officials did not consider this sight good for us, for we were rapidly conducted into the airport building where normal customs and passport business was conducted Each company using the aerodrome had its own section of the building opening from a central waiting-hall From here passengers were called one by one to answer any questions by the passport control, who only asked me if I was married and accepted my "yes" without request for supporting evidence The country between Cintra and Lisbon reminds one of Surrey except for the white houses and the donkey carts The roads are good and the whole place has an air of prosperity not usually seen on the Continent

The stories current in England about the difficulties, and particularly the uncertainties of trans-Atlantic travel seemed gross understatements when one heard about them from actual sufferers It appears that air priorities are worth less than the paper they are written on partly through the irregularities in the service and partly through competing interests for its use The result is that men have wasted weeks of their time in Lisbon till, before the United States came into the war, they transferred in disgust to the American Export Line which kept a weekly service to New York in operation with great regularity

Having sorted out matters at the different offices we all, for different reasons paid a call at the British Embassy, my own purpose being to start arrangements for the return journey The comments in the *News Chronicle* about those in high places obtaining flights to England for butlers and women not on journeys of national importance had not passed unnoticed but in Lisbon the embassy staff is clearly not to blame for happenings outside their control My colleague M had had a room booked for him at the Hotel Aviz and kindly arranged for another one which had to be at the Hotel Berges, quite a good house about a mile distant, more in the centre of the city than Aviz My hotel was comfortable though expensive, but so is everything else in Lisbon except the taxis The drivers of these wonder how long they will remain so owing to increasing petrol shortage which has already caused private cars to be laid up three days a week In the evening M and I dined at the Aquarium Dinner there should start with fish hors-d'œuvres, which could easily be a meal in itself judging by the array of prawns, langoustines and sea snails presented to you A small steak and onions with a bottle of local red wine afterwards proved to be our measure despite the many hours that had elapsed since our aeroplane lunch What with rationing at home and austerity outside I found I had got out of the way of tackling an old-fashioned dinner Next day I talked some shop Through German influence the use of azosulphonamides locally into wounds of any kind seems to be the universal practice Portuguese medicine taken as a whole may not be of a high order but it does seem a pity that little is done to assist it from England, a country to which it looks for guidance

* * *

When Mr Churchill called Mr Aneurin Bevan "a merchant of discourtesy" rather than discourteous I take it that the PM meant that he gathered discourtesy wholesale from his friends and dispensed it retail to his enemies The real reason for much of the crude criticism of the Government, especially from the younger critics, is that the belligerency engendered by the war has found in them no other form of expression They feel they are frustrated in that many of the politicians who played no small part in losing the peace of 1918–39 are still in high office, but if their warlikeness was given some vent their attitude might be more virile and less virulent Perhaps that tardy sanity, which has recently banished the emasculated voice of the crooner from the studios, which has after 3 years of sea warfare made Service decorations open to members of the Mercantile Marine, might next time we land in France invite Mr Bevan, Mr Shinwell, and the like to go with the broadcasters and watch it, not in order to work the Uriah trick on them, but so that the psychological effect of a first-hand encounter with war might benefit them and the Mother of Parliaments

* * *

She's a billeting inspector who has to travel long distances by car on a slender ration of petrol "I ran dry yesterday afternoon," she said, "miles from anywhere, so I put an SOS on the windscreen and went to sleep I was wakened by a tall, handsome man in a car who was travelling in the opposite direction I told him of my plight so he turned his car, produced a rope and towed me to X, where I live I gave him some dinner at a pub and found I had no money, so I got the waiter to cash me a cheque I then got a bed for him at the house of a friend of mine, gave him some breakfast and off he went ' "I suppose you knew him?" I asked 'No, never saw him before in my life" "What was his name? Jack,' she replied Aren't women wonderful?

Letters to the Editor

CONSIDERATE TONSILLECTOMY

SIR —Mr Layton's ideals (July 4 p 24) regarding a close season of 3¼ months for tonsillectomy and an allowance of 20 minutes for each case of tonsillectomy would be hard to achieve in a voluntary hospital where the greatest good of the greatest number must go hand in glove with economy, both of time and of cost Consideration of the time factor in surgical cases may be all wrong and Mr Layton thinks it is, but under the present hospital system, with a limited surgical and nursing staff and a steadily increasing waiting-list, it must go on

We find it difficult to believe that Mr Watson Williams (July 18, p 83) is serious when he suggests that basal narcosis for tonsil operations in children is a luxury We assert that basal narcosis should form an essential part of the preparation for all operations on children, and in our experience its omission has frequently resulted in psychic disturbance, the worst form being an inferiority complex which may persist over years as a serious handicap

We appreciate the points made by Major Belfrage (Aug 8, p 168) In the individual case the induction of anæsthesia in bed is excellent practice, but in batches we find it better to move the patient to the anæsthetic-room or the operating-theatre for the induction and leave the sleeping patients in the ward undisturbed Major Belfrage makes out a strong case for operation on children in the evening This does not appeal to us largely because the difficulties regarding nursing and the presence of the family doctor at the operation in the evening are considerable in this area The nursing staff and the aural house-surgeons here assure us that they have not seen any degree of postanæsthetic restlessness suggesting the need for 'Nepenthe' or any other sedative, and that the patients invariably sleep well the night after the operation We do not consider that the combination of barbiturate and opium is either absolutely safe or foolproof, and for this reason we do not think that the administration of nepenthe for occasional postanæsthetic restlessness should be included as part of the routine technique

Since our paper of June 27 was written, we have had further experience of another 600 cases of basal narcosis with oral pentobarbital soluble ('Nembutal') for tonsil operations and we reaffirm its safety and the benefits that accrue to the patient and all those concerned with the patient's welfare

SICKNESS RATES FOR WOMEN

SIR,—In the special article on the report of the Committee on Amenities and Welfare Conditions in the three women's Services in your issue of Sept 19 (p 343), it is said that "As in industry the sickness rates for women in the Services are about twice as high as those for men' But this has certainly not been the experience of the Post Office which, before the war at any rate, was numerically speaking the largest industry in the country In the five years prior to the war, the average yearly sick-rate of some 35,000 to 42,000 women was never as much as two days higher than that of the men (varying from 120,000 to 135,000) and in most years it was less than a day and a half higher—i e, it was never more than 17 per cent higher Nor as a whole, even in war conditions have the sickness rates of women as compared with men ever approached such a proportion as assumed in the sentence quoted

H H BASHFORD

UNSIGNED REVIEWS

SIR,—I have from time to time been encouraged to protest against the abuses of anonymity under cover of which reviews of books are often published May I take as current example the unsigned review (*Lancet*, Aug 29, p 264) of E B Ford's *Genetics for Medical Students* "The basic concepts are not explained very clearly " is a serious criticism, if true It is not substantiated by any example in the *Lancet* In a signed review of the same book in *Nature*, F W Sansome comments on the ' straightforward and clear manner " in which the author " outlines the principles " If this is a matter of personal opinion surely readers of the *Lancet* deserve to know whose opinion they are reading, so that they may judge whether the writer has one-tenth of Mr Ford's experience in university teaching

The *Lancet* reviewer complains also that human polymorphisms " are perhaps given more place than they deserve in a textbook for students " The reviewer in *Nature* thinks that " chapters on polymorphism answer many problems of the medical and sociological worker "

It is, of course too much to expect of any reviewer to appreciate all sides of a rapidly developing subject I do, however, suggest that those who write publicly over their own names do tend to limit their imputations to points which they really are in a position to substantiate Signed reviews should be encouraged, if only on the ground that the writer whose name is published does usually render better service to the public, on whose behalf he has read the book

Galton Laboratory R A FISHER

SOLDIER'S DOCTOR

SIR —Your leading article of July 1 must have been inspiring reading to the younger generation of doctors and was certainly pleasing to those who passed through the crucible of 1914–18 on active service in the field During the last war all the younger doctors, and many of the older ones, scrambled to get into one or other of the Services at the earliest possible moment Their engagements up till 1917 were only for one year and one of the duties of an ADMS of a division, or commander of a medical unit, was to persuade his officers to carry on from year to year Very few of them " chucked it " and most stayed on in the Services even in the face of heavy financial losses I have not met one who regretted his military service On the contrary one eminent specialist has insisted that his service with the RAMC " made " him Both the present presidents of the Royal Colleges served in the RAMC in the last war

May I emphasise the point you make, " Professional knowledge is not enough to make a first-class army doctor," and did not one of the greatest of physicians and teachers say that the doctor who only knew medicine did not even know that ? Very little consideration must bring home to the young doctors of today the advantage of meeting men outside their own upbringing with different aims in life, and that this is quite as valuable a training for after-life as years of hospital appointments. I am sure that experience gained in the war has left those who have had the advantage of it better doctors than they could have been without

London, E C 4 R J BLACKHAM

DEATH CERTIFICATION AND CONGENITAL SYPHILIS

SIR,—I have read with considerable interest Dr Miller's remarks on certification of death in infancy and your leading article of Sept 5 , likewise the report by Spence and Miller to which both refer It must be obvious to those who have given the matter any consideration that the death certification of infants and young children leaves much to be desired and as matters are at present it is almost valueless statistically Some years ago when discussing the incidence of congenital syphilis with the late Dr T H C Stevenson of the Registrar-General's department I expressed the opinion that the annual figures of that disease as published by the department were fallacious and valueless , for how many practitioners (outside a hospital) would certify a baby's death as being due to congenital syphilis even if they were certain of the diagnosis , in addition to which some atypical cases would be missed

Generations of practitioners have recognised or believed that miscarriages, stillbirths, and premature births were frequently the result of maternal syphilis The Newcastle report mentions that 47 infants under the age of 4 weeks, out of a total of 138 deaths at this age-period, died of prematurity alone and I believe it is highly probable that some of these were the result of maternal syphilis D P R Keizer (*Amer J Dis Child* January, 1940) found syphilis the cause of prematurity in 33 out of 858 cases (3 88%) and possibly more among 259 cases due to " unknown cause " But neither Dr Miller nor your leader so much as mentions the word syphilis, and as no mention is made of antenatal serological blood tests these presumably were not carried out The report itself devotes four and a half lines to syphilis and states that " only one case of clinical congenital syphilis occurred throughout the year and there were *no reasons to suspect other cases except one* [italics mine] in which a mother who had received treatment some years previously gave birth to a premature child which died after a few hours " Some indication of the probable connexion of syphilis with this death from prematurity should, in my opinion have been given in table x of the report (causes of death) The words I have italicised are important because syphilis may be present in a family without there being any reason to suspect it

It is, or should be, common knowledge that conceptional syphilis usually gives no indication of its existence in a woman until the birth of a dead child a premature infant or a syphilitic child, and it is only by the routine blood testing of all pregnant women that such cases can be discovered This is desirable even in peace-time, but in war-time with its inevitable increase in the incidence of venereal disease it is essential if we would do our duty to the state and to the coming generation Surely after 25 years' experience in venereal disease we are not going to repeat one of the tragedies of the last war and allow thousands of congenitally syphilitic children to be born and many of them to die annually In the seaport towns in particular it is imperative that all expectant mothers should be blood tested It may be said that there are not enough serologists left in civil practice to carry out these tests, if that is the case why should not the pathologists who are in the Services help in the matter whilst they are available in this country, and whilst other serologists are being trained? It is an urgent matter and at the moment the nation is one and indivisible

Leatherhead DAVID NABARRO

NITROUS OXIDE ANÆSTHESIA

SIR,—The very balanced viewpoint expressed in your leader " Anæsthesia for the Belly Wound " (Sept 5 p 283), and the fact that those whom you call the " not so expert " are now being called on in increasing numbers to give anæsthetics, prompts me to amplify your few remarks on nitrous oxide with oxygen This as you say, is often the first choice of the not-so-expert anæsthetist, but would, in my opinion, in many cases be better avoided in favour of open ether

Nitrous oxide with oxygen is an anæsthetic agent capable of producing unconsciousness only , it never produces any degree of muscular relaxation Its abuse for the latter purpose always implies suboxygenation, while, as you rightly point out even for the maintenance of unconsciousness suboxygenation is often difficult to avoid In this connexion some recent teaching has been unfortunate The statement, for example, that cyanosis is of no significance in the absence of respiratory obstruction would, I think, be impossible to justify on physiological grounds Many writers have confused the issue by placing undue emphasis on the fact that in cases of plethora cyanosis does not imply anoxæmia, for such cases are rarely seen in the theatre Because patients with polycythæmia are cyanosed in the presence of adequate oxygen, one certainly cannot conclude that cyanosis in other conditions may be disregarded as a sign of oxygen lack The emphasis should rather be placed on the fact that most patients are either anæmic before they come to operation, or become so during its course Such patients may be anoxæmic without showing cyanosis , the more so the greater the degree of their anæmia

In the absence of cyanosis, the recognition of anoxia, especially in its minor degrees, is very subtle Of the signs usually described, alteration in respiratory rate or rhythm is often obscured by premedication while lowered blood-pressure, reduced pulse-pressure and increased pulse-rate are late signs In the light of present knowledge it seems wise to regard all cyanosis (except where the hæmoglobin level is known to be raised) as positive evidence of anoxæmia, while in cases where this level is lowered the only way to avoid anoxia is to increase the oxygen percentage in the mixture *above* the minimum level necessary to keep the patient pink This technique may ften necessitate a supplementary agent to enhance the ffect of the nitrous oxide, and in my opinion the use of uch a supplementary agent is more often evidence of kill on the part of the anæsthetist than of the lack of it Of such agents, ether is in many cases, and especially or the not-so-expert the safest simplest and best If skilfully administered this does not necessarily imply, as many American writers assert, that the gases are used merely to volatilise ether or that the ether becomes the main anæsthetic agent of the mixture Even were this the case, which I doubt the changes produced in tissue cells by anæsthetics skilfully administered are almost certainly reversible Those produced by anoxia, even of minor degrees and especially if prolonged, are as certainly not reversible Expertness of administration, since it cannot mitigate the effects of anoxia shows itself in its recognition and avoidance Thus, the statement that nitrous oxide with oxygen is the safest anæsthetic agent is subject to considerable qualification

Goodmayes, Essex R BLAIR GOULD

VITAMIN C IN PERNICIOUS ANÆMIA

SIR,—I believe the following case-summary supports the view of Dyke Della Vida and Delikat (*Lancet*, Sept 5, p 278) regarding a vitamin-C deficiency in irresponsive pernicious anæmia

A single woman, aged 60, was found to have a severe macrocytic anæmia in March, 1942 On March 24 red cells 2,500,000, hæmoglobin 52%, anisocytosis, poikilocytosis and large macrocytes In spite of massive doses of liver intramuscularly, the reticulocyte response remained very poor, the blood showed little improvement at first, and deterioration later On April 27 the red cell count was 3,200,000 per c mm and hæmoglobin 70% but by May 13 these had fallen to 2,100,000 and 45% It was then suspected that the patient had a carcinoma of the stomach and a hopeless prognosis was envisaged From June 15, 150 mg of vitamin C, in the form of 'Redoxon,' was given daily, the liver injections being continued A clinical response was rapidly apparent, and the blood-picture began to improve after five weeks On July 31 red cells 3,800,000 per c mm and hæmoglobin 52% On Sept 14 red cells 3,900,000 and hæmoglobin 74% The red cells showed no poikilocytosis but distinct anisocytosis and some polychromasia The treatment has been continued and the improvement has been maintained The patient is now ambulant and is gaining weight

My single case did not permit of any valuable inference, but in the light of the three cases now reported in your columns, it seems that vitamin-C estimations in intractable cases of pernicious anæmia may throw further light on this condition and provide a promising line of therapy

London, N W 8 S C LEWSEN

HEN WLAD FY NHADAU

SIR,—Your peripatetic correspondents are always delightful, but none has given me greater pleasure than he who recently has been "standing" in the Market Place at Portmadoc Had not his companion pushed him into his car, indubitably he would have become possessed of a packet of inferior razor blades at an exorbitant price, I recognise this seedy looking individual as an old and amazingly successful importunate friend I assure your correspondent that the Welsh are not a sickly race—kindly and sensitive to suffering in their small community living in this wild land of narrow valleys and knotted hills, but, please, not a sickly race Incidentally, I wonder if one listened to two Englishmen talking Welsh what the conversation would be about Very improbably would it be about the historic occasion centuries ago when not so far away from Portmadoc the Welsh swore fealty to the English, since when none have been more loyal than they, remaining true to the defence of their country and liberty "For these they fight for these they undergo hardships, and for these they willingly sacrifice their lives They deem it a disgrace to die in bed, and an honour to die on the field of battle' Your correspondent will recognise this quotation from the writings of Giraldus Cambriensis, and will I am sure subscribe to them when next he stands (and thinks) in the Market Square at Portmadoc I wish it had been his experience not only to stand, but to see the loveliest view to the peak of Snowdon, and also to hear the music across the bay of the marching men of Harlech which will continue to sustain the valour of the proud people to which I have the honour to belong

EXILED

MD CANTUAR

SIR,—With reference to your note on the Lambeth degrees in the annual Students Number (p 267), I beg to point out that the fourth and last such degree in medicine since the Medical Act of 1858 was granted to James Rogers of Swansea in 1880 Dr Cecil Wall gave a full account of the various recipients of Lambeth MDs and MBs seven years ago (*Brit med J* 1935, ii, 854) An interesting point is the fact that by the letter of the act of 1534, the archbishop is only empowered to grant such degrees as were in use at that date and, as the faculty of surgery is of recent development, it appears that he may not create masters and bachelors of surgery, while being competent to grant the MD and MB With regard to the use of the title it would be perfectly legal for one who is already on the Medical Register to make use of his title if granted a Lambeth degree, even Bye-law CLXVI of the College of Physicians only prohibits its diplomates from assuming the title of MD if they have not obtained a degree—it does not mention whether the MD comes from a university or not

This correspondence draws attention to one serious need in our system of postgraduate facilities, since the Durham (Practitioners) MD was abolished in 1932 no way has been left open for the non-graduate practitioner to obtain a medical degree It was to meet the need of deserving non-graduates in times gone by that the archbishops used their prerogative, and anybody who examines the list of Lambeth MDs will see that they used it wisely and well

Canterbury R R PREWER

LIAISON

SIR,—When in doubt consult the *Oxford English Dictionary*—so I did so The result was something of a shock Liaison means (*a*) a thickening for sauces, (*b*) a close connexion, (*c*) an illicit intimacy (*d*) the joining of a final consonant to a following word commencing with a vowel, and, at last, (*e*) combination and cooperation of allied forces or arms of the same force As a medical officer in the Home Guard I have been constantly exhorted for eighteen months past to liaise (a new verb for the *OED*) with civil authorities and the RAMC This has made me study the conditions necessary for "combination" and "cooperation" Curiously enough most of these conditions are provokingly absent The first condition is that one should know something about the other man's job This can best be found out by asking him It is therefore disconcerting to meet with the reply that there is no order in the civil defence services touching the matter of liaison with the Home Guard, and that pending the arrival of such order nothing can be done about it There are indeed many officers of the civil and municipal services who are prepared to go ahead without waiting for an order but there are still far too many whose attitude is otherwise Another way of learning about the civil defence services is by listening to lectures about them Such lectures are occasionally available, but they are not enlightening for the very good reason that the speakers do not know the job of their Home Guard audiences and are therefore unable to visualise the points most important to them And when some important (to us) question is asked—for example, what is the equipment of an up-graded point—the speaker is found to have no knowledge of the proper answer The obvious remedy is that pre-liaison education should involve addresses by Home Guard medical officers to the heads of local civil defence services I once managed to get permission to give such an address Afterwards, my audience freely admitted that they had had no idea of the possibilities of invasion or of the combined responsibility of the HG and CDS in case of attack Much the same is true of the RAMC One seldom meets with unwillingness to liaise but almost always with a startling ignorance of the size of the HG and of its medical side I have attended three or four official disquisitions upon the organisation of the RAMC (with which most of the HG audience was already pretty well acquainted), but only once have I heard of the RAMC being addressed by a HG medical officer These difficulties might easily be removed, but the initiative would have to come from above, very far above such humble persons as HGMO's

There is another difficulty Not long since I attended a Conference (so important as to deserve the capital letter) at which the highest officers of the HG, the RAMC *and the CDS attended We sat round a table for a long* time Then we had tea and buns made with white flour (prewar stock belike) Then we did some more talking and finally the Chairman, a much decorated officer of the AMS, announced the result, which was that we had demonstrated that the machinery for liaison had been carefully laid down in orders and that there was therefore no more to be said about it The machinery in question amounted to no more than an order that everyone should liaise with everyone else, and, being an Army order, it had not reached the civil authorities and even if it had would in no wise have been binding on them

A matter has arisen which seems to make liaison even more necessary than hitherto *Both the CD* Services and the Red Cross have been exhorted—in a somewhat casual and indefinite manner—to do what the HG has long been doing, namely, to set up minor casualty collecting posts at which the wounded can be retained for a while pending the arrival of ambulances It is apprehended that this arrival may be much delayed in the areas affected by invasion. Surely a combined committee of the three services involved is essential if there is not to be confusion, overlapping and waste of personnel and material But in practice it is almost impossible even to discover what either of the other services is doing about it It is harder still to get any message through to those higher authorities with whom lies the power to compel combination and cooperation So, if invasion comes, our wounded must await any happy chance that utter confusion may vouchsafe them Let no-one believe that this is too harsh a picture In emergency all will no doubt do their best for the wounded , but this is not enough It is within our power as a nation to build up, especially in areas where invasion is most likely, so complete, all-embracing and coordinated a service that all wounded may know beforehand where help can be had, even if all ambulances must be off the roads, even if, as is certain, what ambulances there are prove wholly inadequate for the purpose But for this *purpose effectual liaison is essential now, not a mere* liaison on paper but actual cooperation not less perfect than it has been made, for example, in the fire services And it is for the highest authorities to take this problem in hand The facile excuse that casualties and suffering are inevitable in war will never satisfy HG officers, whose men are their friends and neighbours for whom they feel something more than merely official responsibility

Z M A

MODEL WOUNDS IN FIRST-AID TEACHING

SIR,—I have found model wounds made with 'Plasticine' a useful aid in my course of lectures on first-aid I had considerable experience in dressing injuries of all kinds during the air-raids in this neighbourhood and had the idea of recording them by this method I first had the idea from seeing wax cameos made by Madame Tussaud's father, a French surgeon The principal injuries were caused by broken glass, which inflicted terrible cuts We also had to deal with incised wounds, gashes from flying *stones and shrapnel, wounds with glass* and odd fragments of metal still embedded deeply in them, and of course fractures of all kinds, both simple and compound Having passed through first-aid classes we knew something of how to deal with these cases and prepare them for evacuation to hospital After the raid I noted down the chief injuries and *then as* soon as possible made models in the following manner

I prepared a background of calico smeared with thin plasticine on which I built up the wound with a "worm" of plasticine moulded in the shape of the injury and smoothed down on the outside by my thumb Into the cavity thus formed I inserted broken ends of chicken and other bones according to the size of the real bones that had been fractured I also inserted bits of glass, odd nails and bits of metal to represent other injuries with which we had to deal When the plasticine was set I painted the whole model with bright red paint for arterial hæmorrhage and dark red, almost purple, for venous The calico backing was also painted to match The bones were painted bright red or dull red and the effect was most realistic

When I gave my lectures I had friends to act as patients who were carried into the hall on *stretchers* or limped in if able to walk I had previously fastened the "wounds" on their arms, legs, head, &c by adhesive tape and painted the whole with cochineal To add to the general effect I painted trickles of blood from the nostrils in the case of head injuries and long streams and smears of blood down the face and on the limbs Perhaps my best effort was a "patient" whose abdomen had been ripped open by a bomb This terrible injury was represented by lengths of rubber tubing, painted with cochineal and red paint of various shades, and fastened on with adhesive tape, with the body painted with cochineal She came in screaming and I can assure you the effect was terrific One woman almost fainted when I asked her to attend to this patient, and no wonder *She really looked* awful

Glass gave great trouble and most of my class wanted to pull out the pieces This I had to prevent as it might have cut an artery My "patients" acted their parts with great realism and fully entered into the idea If the class tried to dress their injuries without first of all making them sit down they invariably fainted, and then it was discovered that *a simple fracture* had developed into a compound fracture

I found it essential to rehearse the patients beforehand and coach them in their parts in accordance with their injuries It is far more realistic when "patients" scream and cry when brought in to be dressed, or vary the performance by "fainting"

I shall be happy to show my model injuries to any readers who care to see them

Public Health

From the Annual Reports

RESTRICTIONS on the publication of population figures make rates and numbers in the annual reports for 1941 meaningless, and enforced brevity has shorn accounts *of unusual episodes of most of their value The* reports are thus no more than mark-time statements to ensure continuity of local public-health histories and ill repay the time, effort and material spent on them

Dr Henry Whitehead gives a table of the chief vital statistics of *Wigan* in decennia from 1876 which shows the dramatic changes which have occurred from the years of highest to those of lowest birth-rates In 1876 the birth-rate of Wigan was 48 9, in 1936 it was 17 2 This reduction of nearly two-thirds was regular, but since 1936 the rate has fluctuated with no special trend in either direction The death-rate *fell from 28 5 to* 12 8, since 1936 it has fluctuated with a trend towards increase People born in the seventies are now dying out in the course of nature, but though the birth-rate fell rapidly in each decade from 1870 to 1930, the actual number of births increased, and the death-rates of the future are governed not by the birth-rates but by the actual numbers born a lifespan before There will be no dramatic rise in the death-rate corresponding to the *dramatic fall in the birth-rate during the past* seventy years Neither the zymotic death-rate nor the infantile mortality showed much change before this century The zymotic death-rate was 4 9 in 1876 and 4 1 in 1896, but by 1936 it had fallen to 0 42 and it has fallen further since Roughly in the last quarter of the nineteenth century the zymotic group *killed 5 per 1000 population* annually, it now kills less than 5 per 10,000 This means a saving of 180,000 good young lives annually Infantile mortality was 186 in 1876 and in 1896, but by 1936 it had fallen to 82 The tendency of this rate in the present decade is to vary sharply from year to year, but on the whole the trend is about level Though birth-rates and death-rates are but indirectly influenced by medical science—for all of us are born and all will die—*zymotic death-rate* and infantile mortality are directly, though not exclusively, under medical control In theory we could reduce both to zero , we are getting near to this with the zymotic infections, and we are making headway towards it in infantile mortality

Dr J A Charles of *Newcastle-on-Tyne* compares the statistics of 1914–16 with those of 1939–40 In the early years of the last war the annual averages were birth-rate 27 2, births 7443, death-rate 16 8, deaths 4619, infant mortality 131, infant deaths 978, pulmonary tuberculosis mortality 1·32 and deaths from cancer 267 In 1939–40 the corresponding rates and numbers were birth-rate 16 7, births 4583, death-rate 13 8, deaths 3697, infant mortality 63, infant deaths 287, pulmonary tuberculosis mortality 0 90 and deaths from cancer 466 Notifications of enteric fever numbered 202 in the first two years of the last war, but only 15 in 1939–40

Infectious Disease in England and Wales

WEEK ENDED SEPT 12

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1618, whooping-cough, 1074, diphtheria, 855, paratyphoid, 7, typhoid, 30, measles (excluding rubella), 2644, pneumonia (primary or influenzal) 319, puerperal pyrexia, 125, cerebrospinal fever, 62, poliomyelitis, 20, polio-encephalitis, 2, encephalitis lethargica, 1, dysentery, 146, ophthalamia neonatorum, 76 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 1 (0) from measles, 3 (1) from whooping-cough, 17 (0) from diphtheria, 73 (6) from diarrhœa and enteritis under two years, and 3 (0) from influenza The figures in parentheses are those for London itself

West Hartlepool reported the fatal case of enteric fever Liverpool and Birmingham each had 6 deaths from diarrhœa

The number of stillbirths notified during the week was 226 (corresponding to a rate of 37 per thousand total births), including 17 in London

---

Obituary

DAVID WATERSTON

M D EDIN, F R C S E, F R S E

Professor Waterston, who died in an Edinburgh nursing-home on Sept 4, in his seventy-second year, following a persistent pneumococcal infection, was an anatomist and anthropologist who made excursions into physiology He was of the Edinburgh school and all his life retained the hallmark of his association with his chief, Sir William Turner He qualified in 1895 and after twelve years as demonstrator at Edinburgh University was called to the chair of anatomy at King's College, London, in 1909 When five years later he succeeded the late James Musgrove, in the Bute chair, at St Andrews, it was a home-coming for him, for his father had been a minister in Dundee, and he was quickly accepted both by town and gown For six years Waterston represented the senatus on the university court and from 1930–40 the university on the GMC He was lately coopted a member of the town council He had been associated with Sir James Mackenzie in the foundation of the Institute of Clinical Medicine, and it was here that he carried out his investigations into cutaneous pain (*Lancet*, 1933, i, 943), and made the examination of Mackenzie's heart for which he had left instruction

The department of anatomy, founded by Musgrove, although never large in numbers, was developed by Waterston into an excellent school He was a brilliant teacher and knew how to illustrate his lectures with the neatness and skill shown to great effect in *The Anatomy in the Living Model* (1931) He also edited the *Edinburgh Stereoscopic Atlas of Anatomy* Outside medicine his interests were mostly anthropological A collection of his arrow-head flints is in the Bell-Pettigrew museum, and when St Salvator's College Chapel was being renovated he examined the skeleton of Bishop Kennedy and reported on his findings to the Royal Society of Edinburgh

In 1907 Waterston married Isabel Amv Simson, and they had three sons Two are serving with the RAMC, the eldest in India and the second in the Middle East

JOHN MacMILLAN

M B ABERD, MAJOR R A M C

John MacMillan was a delicate boy who early set his heart on becoming a doctor though his friends at the Aberdeen Grammar School sometimes wondered whether his physique would allow him to do so, and indeed throughout his student days he had to contend with recurrent attacks of illness But though outwardly shy and diffident he was resolute of purpose and he graduated in 1936 He held resident posts at Walsall and Kettering general hospitals and spent eighteen months in general practice, but he had chosen public-health work as his career and shortly before the outbreak of war he was appointed ARP assistant MO for Southgate He was combining this job with a course for the DPH, but when war broke out as member of the Territorial Army he was called up at once and sent to the Middle East at the beginning of 1940 He served in Palestine, Iraq and Syria and was mentioned in dispatches in April, 1941 He died on active service last July and leaves a widow who is also a graduate of Aberdeen

ALWYNE THEODORE COMPTON

F R C S

Mr A T Compton, who died on Sept 9 at the age of 68, had been connected with the German Hospital in Dalston for 30 years He retired to Seaton in 1938, but after the outbreak of the war he returned to the hospital where almost immediately he had a cerebral hæmorrhage with left hemiplegia, from which he did not perfectly recover Compton qualified from St Bart's in 1901 taking the surgical fellowship in the following year and later lecturing on anatomy at King's College His *Essentials of Surgery* was a textbook in brief with a sound basis of surgical anatomy and pathology Patients at the hospital will miss him for he was always kind to them His case-notes mostly contained illuminating drawings From his father, a well-known landscape painter, he doubtless derived not only his skill as a draughtsman, but also his love of walking and Alpine climbing

DONALD SEYMOUR SCOTT

M B CAMB, M R C P; LIEUTENANT R A M C

Donald Scott, known to his friends as "Popa," was educated at Felsted School, where he was head of Follyfield House when he left in 1929 He went up to Emmanuel College, Cambridge, where he was a member of the OTC, played hockey for the Wanderers, and became an enthusiastic yachtsman He qualified from the London Hospital in 1935, and took his degree two years later A friend remembers him as one of the most contented and happy of men (seldom seen without a pipe), and he knew how to communicate his happiness to others After holding house-appointments at the London Scott was appointed RMO at the Royal Masonic Hospital in 1938, and following some months in general practice he took the MRCP When war broke out he joined up at once and was posted to a field ambulance under orders for overseas, and he was sent to France with his unit in January, 1940 In May of that year, while attending casualties in a forward dressing station, he was seriously wounded by an exploding shell He was taken to a French hospital at Zudvcote, and it has now been officially presumed that he died there of his injuries, although no definite information has been obtained He was 29 years of age

---

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW —The honorary fellowship of the faculty has been conferred on Mr Geoffrey Jefferson, professor of neurosurgery in the University of Manchester

Lectures on Dermatology

The following lectures on common skin diseases are to be held at the London School of Dermatology, 5, Lisle Street, W C 2, at 4 30 P M on Tuesdays and Thursdays Sept 29, Dr Henry Corsi, scabies and parasitic infections, Oct 1, Dr William Griffith, bullous eruptions, Oct 6, Dr R T Brain, ringworm infections, Oct 8, Dr J E M Wigley, general principles of treatment, Oct 13, Dr A D Porter, eczema, and Oct 20, Dr Geoffrey Duckworth, seborrhœic dermatitis and psoriasis

The lectures are free and open to medical officers of all the Allied Forces, postgraduates and undergraduates

London County Council

For the duration of the war St Peter's Hospital, Whitechapel, and St Luke's Hospital, Chelsea, have been transferred from group I of the council's hospitals, which receive the acute sick, to group II which receive the chronic sick

Hospitals in the North-east

By arrangement with the Minister of Health, the Nuffield Provincial Hospitals Trust has appointed Prof J A Ryle, FRCP and Dr A E Quine, FRCS, to carry out a survey of hospital services in the north east of England (Northumberland, Durham and Cleveland) This survey will be conducted on the same lines as the surveys now being carried out by officers appointed by the Minister of Health in the London area and in the north west This is part of an arrangement under which the Nuffield Trust, with the concurrence of the County Councils Association, the Association of Municipal Corporations and the British Hospitals Association, has undertaken to assist the ministry by organising surveys of hospital services in various parts of the country The areas to be surveyed and the officers to be appointed will be agreed between the minister and the trust

Registrar for Forty Years

Mr Robert Brough, registrar of the general council of the University of Glasgow and acting secretary of the university court, retired at the end of July after almost forty years' service The council are organising a testimonial to him which many Glasgow graduates will wish to join Subscriptions—which are limited to 5*s*—should be sent to the clerk of the council at 82, West Regent Street, Glasgow, C 2

Chiropodists Wanted for ATS

The care of the feet is an important part of the medical services of the ATS, and foot complaints sometimes occur within the first few weeks of enrolment, probably because most women entering the service have been used to wearing high heeled light weight shoes These women show symptoms of metatarsalgia, early foot strain, tendo Achillis bursitis and so forth, and an appeal is now being made to women chiropodists up to the age of 43 (50 for ex Service women) to enrol in the ATS They will be sent to a basic training centre for one month, and afterwards posted, with the rank of corporal, to ATS groups or training centres They will be paid at the rate of 4*s* 6*d* a day—the highest trade rate for an ATS corporal On being posted to a company, in view of the specialised nature of their work, they will not be expected to undertake some of the more arduous duties which fall to the lot of an NCO All chiropodists work under the direction of a medical officer, and cases which do not respond to treatment are referred to an orthopædic surgeon in a hospital It is intended to have a corporal chiropodist for every 600 auxiliaries Some of them will be stationed in training centres and mixed batteries, others will travel from one company to another in order that regular inspections may be given

Nursing Policy in West Africa

Mr Harold Macmillan, under secretary for the Colonies, replying to a question in the House of Commons stated the declared policy of the Government that there should be no discrimination on the ground of colour in filling appointments in West Africa The Secretary of State attaches importance to the increased employment of colonial men and women in their own countries provided that they are suitably qualified not only by professional attainment but also by personality and character To ensure that these requirements are met, candidates for the Colonial Nursing Service, whatever their origin, are interviewed by the Overseas Nursing Association on behalf of the Secretary of State, and appointed or rejected on its report In order that the present satisfactory status of that Service may be maintained, it is of importance that there should be no lowering of the standards which have been applied in the past and they must be applied to all races without discrimination, even though this may seem to bear hardly on candidates who may not have enjoyed the same educational or cultural advantages as others, but it is to be remembered that candidates selected for the Colonial Nursing Service are often required to carry out, even in their first year of service, duties in regard to hospital supervision and training of subordinate staff which here would only be expected of matrons or sister tutors with long nursing experience Consideration is being given in the formulation of postwar plans to schemes providing Government assistance for sending selected girls to this country to train as nurses, but the number who can thus be accommodated is limited by the number of vacancies which can be made available in teaching hospitals for overseas candidates While this scholarship scheme may help, it cannot possibly provide nurses on the scale requisite for the proper staffing of colonial hospitals and health departments, and it is essential to arrange for training facilities as nurses for girls in their own countries and to supply sister tutors trained in the teaching methods and discipline common to hospitals here After qualification colonial nurses who had been specially selected for ability and character, could then be brought to this country for special courses, and plans are in hand for improving after the war the facilities for providing such courses

Births, Marriages and Deaths

BIRTHS

DUFFY —On Sept 12 at Stourport on Severn, the wife of Captain C A Gavan Duffy, RAMC—a son

FRESHMAN —On Sept 15 at Wingham, Nr Canterbury, the wife of Edgar Freshman FRCS—a daughter

HEWITT —On Sept 14 at Radlett, Herts, the wife of Major E J C Hewitt, RAMC—a daughter

LACK —On Sept 11, at West Cross, Swansea, the wife of Captain Christofer Lack, RAMC—a daughter

PARISH —On Sept 14, at Southborough, the wife of Dr T N Parish—a son

SQUIRE —On Sept 15, in London, the wife of Dr Christopher Squire—a son

TOWNSLEY —On Sept 13, at Norwich, the wife of Norman Townsley, FRCS—a daughter

WAYMOUTH —On Sept 14, at Harrow on the Hill, the wife of Captain Arthur Waymouth, RAMC—a daughter

MARRIAGES

ADAM—FORSYTH —On Sept 19 in Edinburgh Patrick Alan Adam, surgeon lieutenant RNVR, to Isabel Jean Forsyth

GRANGER—ELLIS —On Sept 12, at Kimbolton, Allan Frederic Granger, captain RAMC, to Phyllis Mary Ellis

GREGG—WILKINSON —On Sept 12, in London, Duncan McCallum Gregg to Audrey Ann Wilkinson

HAY—OLIVER —On Sept 11, at Newcastle on Tyne, Rankin Kilgour Hay, MB, to Winifred Oliver, SRN

HORTON—JENKINS —On Sept 14 at Belmont, John Anthony Guy Horton, MB, to Margaret Jenkins

DEATHS

BRIERLEY —On Sept 11, at Kitamaiyu, Ruiru, Kenya Colony, Wilfred Edward Brierley, MB MANC and LEEDS, FRCS, lieut colonel IMS (retd)

CHATER —On Sept 17, at Petersfield Harold John Chater, MRC, surgeon rear admiral RN (retd), aged 68

COTES PREEDY —On Sept 16, at Gerrards Cross, Digby Cote Preedy, LSA, KC

GELL —On Sept 14, at Church Aston Manor, Henry Willingham Gell, OBE, BM OXFD aged 85

GRIMMER —On Sept 16 George Kerr Grimmer, BA NEW BRUNSWICK, MD EDIN, FRCSE of Trinity Crescent London, S W 12, aged 76

LLOYD JONES —On Sept 16, Ernest Lloyd Jones, MD CAMB, formerly of Cambridge, aged 79

MOODY —On or about Sept 11, at Umvuma Southern Rhodesia, John Evelyn Moody LMSSA formerly of Scarborough, aged 61

PHILLIPS —On Sept 11, at Farringdon, Hants, Alfred Stanbury Phillips, MRCS formerly of Bedford

PLUMPTRE —On Sept 14, at Cheltenham Cyril Macdonald Plumptre, FRCSE, FRCOG lieut colonel IMS (retd) of Wendover

RENDEL —On Sept 13, at Godalming, Frances Elinor Rendel, MB LOND

WRIGHT —On Sept 9, at Liverpool, Hedley Duncan Wright, BA TASMANIA, MD, DSC EDIN MRCPE, professor of bacteriology in the University of Liverpool

The Index and title-page to THE LANCET, Vol I, 1942, which was completed with the issue of June 27, will be ready shortly A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

LID-RETRACTION IN TOXIC DIFFUSE GOITRE

K C EDEN, M S LOND, F R C S
SURGICAL REGISTRAR

W R TROTTER, D M OXFD, M R C P
ASSISTANT TO THE MEDICAL UNIT

UNIVERSITY COLLEGE HOSPITAL

(From the hospital clinic for the study of thyroid disease)

APPARENT protrusion of the eyes is a characteristic eature of toxic diffuse goitre (primary thyrotoxicosis, Graves's, Parry's or Basedow's disease), but in a large proportion of such cases the protrusion is illusory, the ppearance being caused by retraction of the upper lid This phenomenon of lid-retraction has long been decribed as Dalrymple's sign, but until recently has often been confused with exophthalmos For this reason the elation of lid-retraction, as distinct from exophthalmos, o the different factors operative in thyrotoxicosis has eceived scant attention in published work It is our purpose to sketch the outline of this relationship

Recent interest in the eye signs of thyrotoxicosis has argely been focused on two striking forms of exophthalmos the clinical syndrome of exophthalmic ophthalmoplegia and the experimentally produced exophthalmos which follows the injection of anterior pituitary extracts In the production of both these conditions (which seem to be closely analogous) thyroid toxæmia plays little part On the other hand, the evidence presented in this paper suggests that in the production of lid-retraction thyroid toxæmia is an important factor It is plainly not the only factor, however, and the conclusion we have come to is that while exophthalmos occurring in toxic diffuse goitre is extrathyroid in origin, lid-retraction is controlled not only by an extra-thyroid factor but also as a rule by thyroid activity

In the recognition of lid-retraction we have made use of Pochin's (1938, 1939) simple and lucid account of the physical signs The distinction between exophthalmos and lid-retraction can readily be made by observing the eyes when they are directed horizontally forward If a band of white sclera can be seen above the iris lid-retraction is present (fig 1*a*), if sclera is visible below the iris this denotes exophthalmos (fig 1*c*) Since the upper lids normally rest some 1–3 mm below the limbus, lid-retraction may be said to be present if the lid margins rest at or above the upper edge of the iris In the case of exophthalmos no such precise statement can be made, for the range of normal variation is wide, consequently we have accepted only the gross cases, in which the lower lids are 2 mm or more below the lower border of the iris, as examples of true exophthalmos When lid-retraction and exophthalmos coexist, sclera is visible above and below the iris (fig 1*b*)

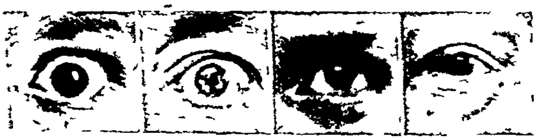

Fig 1—Eye signs in toxic diffuse goitre *a* lid retraction, *b* lid-retraction with exophthalmos *c* exophthalmos, *d* puffy swelling of the lids

The actual recognition of lid-retraction is thus a simple matter, but it can exist in two forms, constant and spasmodic In only the constant form is the relationship to thyroid disease at all clear, and the two have therefore to be carefully distinguished The act of staring is essentially a momentary retraction of the upper lids by the levator palpebræ superioris muscles, and differs only from the lid-retraction of thyrotoxicosis in that it is a transient voluntary action For this reason it is important to eliminate any element of staring when eliciting lid-retraction, and this is perhaps best achieved by asking the patient to look at a distant object In some people even without staring the upper lids may from time to time retract above the eyeball in an irregular and spasmodic manner Though this spasmodic lid-retraction is probably more common in thyrotoxic subjects and is sometimes superimposed on true lid-retraction, it is too common in normal people to be of any diagnostic significance The lid-retraction which is so prominent a feature of toxic diffuse goitre is essentially constant in character, at no time do the upper lids fall below the limbus when the eyes are in the standard position

Apart from thyroid disease, lid-retraction is found occasionally in severe myopia, in lesions of the posterior commissure of the brain (due to encephalitis, disseminated sclerosis, cerebral tumours, &c) and as a congenital defect In all these connexions it is rare In thyrotoxicosis lid-retraction is common, but as a rule is found only in association with toxic diffuse goitre Thus in a series of 254 cases of goitre under observation there were 74 with lid-retraction, 72 of which were cases of toxic diffuse goitre the other 2 being examples of toxic nodular goitre (table I)

TABLE I—RELATIVE INCIDENCE OF LID RETRACTION AND EXOPHTHALMOS IN 254 CASES OF GOITRE

—	Total cases	With lid retraction	With exophthalmos	With exophthalmos or swelling of the lids (concealed exophthalmos)
Toxic diffuse goitre	134	72 (54 %)	36 (27 %)	56 (42 %)
Non toxic diffuse goitre	21	0	0	0
Nodular goitre (toxic and non toxic)	99	2	0	0

It will be seen that lid-retraction occurred in more than half the cases of toxic diffuse goitre, it was a more characteristic feature, in fact, than exophthalmos Only 19 of these 72 cases of toxic diffuse goitre with lid-retraction were associated with exophthalmos as estimated by the position of the lid margin, but there were a further 20 cases with puffy swelling of lids (fig 1*d*), which in our opinion should properly be regarded as concealed exophthalmos[1] Thus it may be said that over half the cases of lid-retraction in toxic diffuse goitre were associated with exophthalmos in a manifest or concealed form

The cases have been further analysed according to age, sex, and duration and severity of the disease, but the results showed no statistically significant correlations so we have not recorded them here Our figures showed a tendency for the incidence of lid-retraction to increase with the severity of the disease, whether this was assessed clinically or by the basal metabolic rate The figures are, however, too small to carry any conviction

RELATION TO THYROID TOXÆMIA

We have evidence of two kinds to demonstrate the relation of lid-retraction to thyroid toxæmia These consist of observations of the effect on lid-retraction, first of treating the disease, and secondly of giving thyroid extract

Effect of treatment—A group of 12 cases of toxic diffuse goitre with lid-retraction was observed for periods ranging from 2 to 24 months without treatment, during which time the disease remained active In all cases the lid-retraction persisted throughout the period of observation, while in 2 it increased In cases treated either by thyroidectomy or conservatively, on the other hand, with improvement of the general condition the lid-retraction tended to clear up (fig 2) Table II summarises the combined findings in 55 cases with lid-retraction treated surgically (all of which improved), 4 cases which improved spontaneously, and the 12 cases, referred to above, in which the disease remained active It is clear that

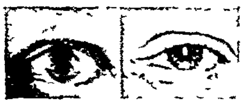

Fig 2—Abolition of lid retraction by thyroidectomy *a* before operation showing lid retraction without exophthalmos *b* after operation showing complete absence of lid retraction Note that the position of the lower lid relative to the iris is unaltered

---

[1] The loose puffy swelling which occurs in the upper lids and along the supraorbital ridges is known as Enroth s sign (fig 1*d*) Occasionally there is also a baggy swelling of the lower lids Both these changes are probably due to accumulation of œdematous subcutaneous fat resembling the fat found in the orbit in clinical and experimental exophthalmos It is logical, therefore, to regard Enroth s sign as denoting concealed exophthalmos

TABLE II—EFFECTS ON LID RETRACTION OF TREATING OF THE TOXIC GOITRE IN 71 CASES

Result of treatment of toxic goitre	Cases	Lid retraction			Increased
		Disappeared	Decreased	Unchanged	
Good	38	29	4	4	1
Fair	21	11	6	4	0
No improvement	12	0	0	10	2

The result was counted good if the patient was left without residual signs of thyrotoxicosis (eye signs excepted) and a resting pulse rate of 80 per min or less, fair result was any improvement falling short of this Duration of observation ranged from 2 to 26 months after operation

in most cases the presence of lid-retraction depends on activity of the thyrotoxicosis Fig 3 shows that in most cases the lid-retraction disappeared rapidly as the disease became quiescent, but it is noteworthy that in a few cases there was a lag of many months between the disappearance of the thyrotoxic signs and that of the lid-retraction We found no evidence to suggest that this persistence of lid-retraction was related to the length of time it had been present

Effect of thyroid extract—In one case the correlation between the administration of thyroid extract and the presence of lid-retraction has been remarkably precise

CASE 1—A woman of 50 gave a 2 year history of chronic ill health with loss of weight She showed all the main features of toxic diffuse goitre, the pulse rate being 80–100 and the BMR + 63%, + 47%, + 42% There was bilateral lid retraction, both upper lids lying 1 mm above the limbus, but no exophthalmos Subtotal thyroidectomy was followed by abolition of all the toxic signs including lid retraction By the fifth month after operation the full clinical picture of myxœdema had developed The BMR at this time was − 15%, − 13% After the administration of thyroid extract (BP) gr 1 daily, increasing up to gr 4 daily, the signs of myxœdema disappeared Whenever the dose of thyroid extract reached gr 3 daily, lid-retraction reappeared (fig 4)

Brain (1936) has described a case in which the eye signs of toxic goitre followed long administration of thyroid extract to a patient suffering from adiposity It is evident from his photographs that lid-retraction was the prominent feature, and that this disappeared when the thyroid extract was discontinued Nevertheless lid-retraction cannot be a common consequence of thyroid medication We have seen, for example, 2 cases in which sufficient extract had been given to produce auricular fibrillation, yet lid-retraction did not appear, one of these cases is more significant in that lid-retraction had been present before thyroidectomy for toxic goitre

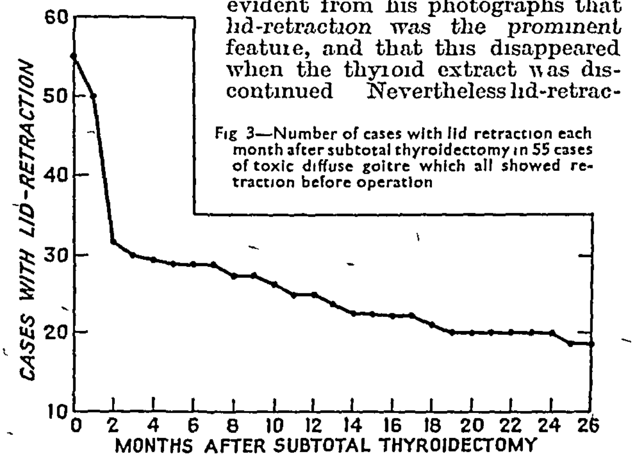

Fig 3—Number of cases with lid retraction each month after subtotal thyroidectomy in 55 cases of toxic diffuse goitre which all showed retraction before operation

THE EXTRATHYROID FACTOR

The fact that lid-retraction does not develop in much more than half the cases of toxic diffuse goitre, that it is not even universal in the severe cases, and that it is seldom encountered in toxic nodular goitre or in patients treated with thyroid extract suggests that thyroid toxæmia is not the sole exciting factor This conclusion is reinforced by those cases in which lid-retraction persists after adequate thyroidectomy and those in which there is a long interval between the disappearance of the toxic signs and of the lid-retraction

A consideration of cases of exophthalmic ophthalmoplegia provides some information about the nature of the extrathyroid factor concerned in lid-retraction In his study of 31 cases of this syndrome, Brain (1938) states that retraction of the upper lids is usually present, while Rundle (1941) found that two-thirds of his 15 cases had lid-retraction Many of these cases show no evidence of thyroid over-activity, and in fact myxœdema is not uncommon We have recently observed a case associated with well-marked myxœdema Such cases in which exophthalmos and lid-retraction develop together in the absence of thyroid toxæmia necessitate another and common causative factor The close analogy between exophthalmic ophthalmoplegia and experimental exophthalmos suggests that this factor is the anterior pituitary secretion The interaction of these two factors is illustrated by the two following cases

CASE 2—A girl of 19 consulted an ophthalmologist for prominence of the right eye which she had noticed for 4 months She was in good health and at full work, her weight was increasing and she had had no breathlessness, palpitations or other symptoms of thyrotoxicosis Apart from unilateral lid retraction without exophthalmos, there were no thyrotoxic signs, the thyroid gland was impalpable, the pulse rate was 80 and the BMR + 19%, + 11%, + 16% During the next 8 months her weight gradually fell and her pulse rate rose Examination then showed a moderate diffuse enlargement of the thyroid, a pulse rate of 100–110 and a BMR of + 52% + 46% Subtotal thyroidectomy was performed with satisfactory result, the lid retraction disappeared after 2 months and has not reappeared a year later

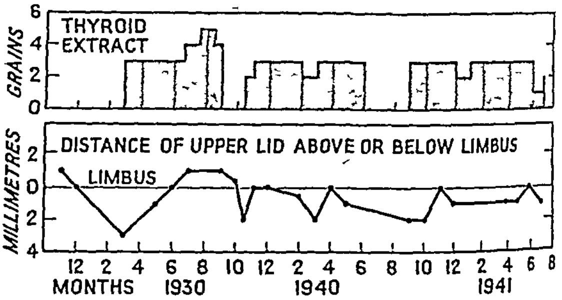

Fig 4—Relation of lid retraction to dosage of thyroid extract in a case of myxœdema after thyroidectomy for toxic diffuse goitre Lid retraction was judged to be present when the upper lid lay at or above the limbus

The fact that lid-retraction could occur at a time when the only sign of thyrotoxicosis was a doubtful elevation of the BMR suggests that some other factor was active, yet the disappearance of the lid-retraction after thyroidectomy implies that the thyroid toxæmia played an essential part in its presence Apparently this was a case in which a very mild thyroid toxæmia was able to potentiate the extrathyroid factor

CASE 3—A woman of 40 gave a history of progressive loss of weight, increasing nervousness and prominence of the eyes for 9 months There was a uniform small enlargement of the thyroid gland, fine tremor of the fingers and a hot moist skin The left upper lid was retracted so as to expose 1 mm of sclera above the limbus, the right upper lid fell just below the limbus, and both lower lids reached the lower border of the iris There was slight supra orbital puffy swelling but no exophthalmos The pulse rate was 108–129 and the BMR + 54%, + 48% Subtotal thyroidectomy was carried out and 2 months later the patient was well, putting on weight, the pulse rate was 80 and the lid retraction had disappeared, 6 months later she was complaining a good deal of the cold and there was a suggestion of myxœdema in her appearance, the pulse rate was 88 and the BMR − 10% At this time the eyes showed slight exophthalmos, 2 mm of sclera being exposed below the iris on each side In addition the left upper lid again rested on the limbus The myxœdema subsequently did not materialise and her condition has remained satisfactory The exophthalmos has continued to increase slightly in the right eye, 16 months after operation lid retraction developed in the right eye and has persisted since In addition there is now slight limitation of full lateral movement in both eyes

The first time this patient developed lid-retraction it was associated with the clinical picture of toxic diffuse goitre and was shown to depend on the presence of thyrotoxicosis The second time she developed lid-retraction it was associated with the clinical picture of exophthalmic ophthalmoplegia, and there was no thyrotoxicosis The same phenomenon, appearing twice in the same subject in a limited time, suggests that a common factor was present throughout At first this common factor could only produce lid-retraction when thyrotoxicosis was also present, later it became strong enough to do so on its own Since overactivity of the anterior pituitary gland has been put forward as the cause of both toxic diffuse goitre and exophthalmic ophthalmoplegia it seems reasonable to suggest that it may be the common factor in this case Whether this suggestion proves to be correct or not the case is interesting as providing a link between the lid-retraction of toxic diffuse goitre and the lid-retraction of exophthalmic ophthalmoplegia As a complete illustration of our views on the subject it forms a convenient ending to this article

SUMMARY

Lid-retraction is, like exophthalmos, a characteristic feature of toxic diffuse goitre The two conditions are easily separable clinically, though both give the impression of prominence of the eye Lid-retraction was present in 72 (54%) of 134 cases of toxic diffuse goitre, in 39 cases being associated with true or concealed exophthalmos

Unlike exophthalmos, which is apparently extrathyroid in origin, lid-retraction usually disappears when the thyrotoxicosis becomes inactive, although occasionally it appears or persists in the absence of active thyrotoxicosis Lid-retraction therefore appears to be governed by two factors, one of which is derived from the thyroid, the other must come from another source (possibly the anterior pituitary gland)

INGUINAL HERNIA AT AN RAF HOSPITAL

HUGH R ARTHUR, M B LOND, F R C S E
SQUADRON-LEADER, SURGICAL SPECIALIST RAF

THE types of inguinal hernia with which we have to deal in the surgical division of an RAF hospital are, of course, limited both by the average age of the patients and by preliminary selection of the medical boards, but many surgical specialists are being called upon to deal with this common complaint, and it is important that the recurrence-rate should be the lowest possible In radical cure the surgeon must give more prominence to the time factor than he did in peace-time Durability of the repair remains the first consideration, but time in hospital becomes almost equally important Many of the cases we see in surgical outpatients occur in men who have finished, or are just finishing, technical courses and are awaiting posting to squadrons Thus it is necessary to find a technique which will enable them to be fit for duty in the minimum time and with the minimum prospect of a recurrence. In the age-group concerned such factors as chronic bronchitis, advanced atrophy of the abdominal muscles and excessive size of the hernia are seldom seen and rarely need to be taken into account when assessing the value of the various methods of repair

CLINICAL FINDINGS AND PRINCIPLES OF REPAIR

During the past 17 months 232 cases of inguinal hernia have been admitted for radical cure, 199 of these were seen in surgical outpatients first and the remainder were admitted direct on the advice of unit medical officers Of the outpatients 21 (11%) refused operation for various reasons and these were fitted with trusses

Hernias seen were divisible into the following types indirect 178 (77%), direct 28 (12%), recurrent 15 (6%), associated with undescended and ectopic testicle 11 (5%) The first two types were composed largely of patients who had had inguinal hernias for a varying number of years before coming into the Service In the remainder of this group the rupture had either occurred during some unaccustomed exercise, often the drill and physical training of the recruit's course, or else had been completely unnoticed by patient or MO until found at some special medical examination (e g, for air crew) The third type almost invariably gave a history of onset following hard manual labour (e g, cranking heavy lorries) and was of interest in that the recurrence often seemed to take the form of a complete new sac of the congenital indirect type Reference will be made to this point later in this paper The last type was usually sent for consultation because of some symptom arising from the undescended or ectopic testicle the hernia if present clinically being of secondary importance, at any rate in the patient's view

In assessing the principles on which a satisfactory repair must be based, it is instructive to analyse the basic lesion in each group In the first group the primary lesion is the presence of a congenital sac, it is reasonable to suppose that there is also some weakness of the floor of the inguinal canal and the very fact that this may be present seems to exclude those methods of repair which rely on the removal of the sac alone In the second group the weakness of the floor of the canal dominates the picture and, in our experience, the peritoneal bulge which forms the sac does not appear through the fibres of an attenuated conjoined tendon but through the gap between the lower edge of the tendon and the deep surface of the inguinal ligament I have also noticed that in a number of these cases the sac is not a true direct sac internal to the deep epigastric artery, but is often a bulge of peritoneum between this artery and the internal abdominal ring, displacing the artery inwards These facts suggest that in certain cases the fault is in the mechanism for closing the inguinal canal as much as in any weakness of the muscle itself The third group, cases of recurrent hernia, accounted for 6% of the recorded series On clinical examination there appear to be two types the first presented the clinical features of an inguinal hernia of the congenital variety, the second was of the direct type, occurring at the lower end of the scar and protruding through a gap between the insertion of the conjoined tendon and the lower attachment of the inguinal ligament Turner (1919) makes clear this division of recurrence into two types but draws the erroneous conclusion that the second type occurs because of weakness of the intercolumnar fibres of the external oblique following previous operation While it is true that this may be a contributory factor it must be obvious that if the floor of the canal is adequately repaired some weakness of these fibres will not itself be responsible for this type of recurrence At operation the most notable feature was the weakness of the scar tissue uniting the conjoined tendon to the inguinal ligament and in many cases its incompleteness, so that a gap was left both at the upper and lower ends The fourth group requires no further mention since the hernial lesion is always congenital and the same remarks apply as in the first group

The following principles emerge

1 The dissection of the sac must be complete so that no part of the neck remains to be a starting-point for a new sac

2 The lowest part of the gap between the conjoined tendon and inguinal ligament must be closed with the greatest possible care

3 Special measures are necessary to secure a firm union between the tendon and the inguinal ligament, simple catgut stitches being insufficient

I would add to these three principles two fundamental considerations of general surgical technique which have been emphasised by Wakeley (1940) first, the normal anatomy of the part should be restored rather than an artificial buttress produced which will stretch and weaken with advancing years, and secondly, adequate hæmostasis is essential at each step of the operation. These well-known surgical truths cannot be overemphasised so long as herniorrhaphy is regarded as an exercise for the junior surgeon rather than a procedure of major importance

OPERATIVE TECHNIQUE

Operative cure of inguinal hernia has occupied the attention of surgeons for many centuries Even in

Roman times Heliodorus described an operation for excision of the hernial sac and stressed the necessity for its complete removal as a safeguard against recurrence During the intervening period this truth sank into oblivion, as did many others, and was only rediscovered at the beginning of last century The earlier surgeons—Czerny and others—contented themselves with removing the sac and repairing the external ring, and it was not until Bassini and Halstead (1890) advised repair of the floor of the inguinal canal by suturing the conjoined tendon to the inguinal ligament that it was possible to operate on an inguinal hernia with any measure of success Of these two operations, the Halstead technique, with its displacement of the cord to the subcutaneous tissues and cutting of the arching fibres of the conjoined tendon, has rightly fallen into disuse on the grounds that it fails to restore the normal anatomy The Bassini technique, on the other hand, has survived in principle, through an enormous variety of modifications, because of its strict adherence to the anatomical principles of the inguinal canal

Other techniques have from time to time been advanced Turner (1919) asserted that in healthy young adults no repair was needed other than removal of the sac, provided the intercolumnar fibres of the external oblique were left intact This dictum is not generally upheld nor would it be a safe one in which to trust under Service conditions where long postoperative abstinence from hard manual labour is impossible Injection treatment has also been tried Halsted (1893) mentions it and lately it has been revived by a few surgeons, but it can be dismissed at once from the Service point of view as being both too protracted and too uncertain in its results

Lately two main schools have arisen the first, originating with Gallie and Le Mesurier (1924), favours autogenous fascial grafts, the second, sponsored by Ogilvie, Maingot (1937), Sampson Handley (1941) and others, advocates the use of floss-silk or linen thread rather than fascia Both schools have produced good results, but in each case the method used has drawbacks The Gallie method requires a second long incision in order to obtain the fascia, and this not only adds considerably to the time of the operation but produces a lesion in the thigh which may give rise to hæmatoma and subsequent disability from muscle hernia The second method demands the introduction into the tissues of a large amount of unabsorbable material with consequent danger of over-stimulation of the tissues and wound infection—an extremely serious matter in an essentially clean operation Both have their uses, in large ventral hernias in young adults several fascial strips may be needed to fill in the defect, and in the elderly patient with little or no muscle tissue left a lattice of permanent silk or linen is undoubtedly an excellent way of creating a plaque of fibrous tissue to retain the abdominal contents, but neither of these techniques fulfils the requirements of the average hernia in a Service patient

The following is a description of the operation which we have adopted more or less as a routine, it is a modification of the fascial graft technique described by McArthur (1904) The principles of this technique were introduced to me by Group-Captain Geoffrey Keynes, but the modified procedure, as described below, I evolved subsequently

The usual inguinal incision is made and the external ring identified The external oblique aponeurosis is divided in the line of its fibres and the inguinal canal laid bare The edge of the conjoined tendon is dissected out and the cord freed, great care being taken to preserve both the ilio inguinal and iliohypogastric nerves The sac is next identified, cleaned, transfixed and ligatured at the uppermost limit, the operator making sure that no part of the neck remains, and the stump is sutured to the deep surface of the transversalis muscle Four No 2 catgut sutures are now inserted between the conjoined tendon and the inguinal ligament, after they are all in place they are tied, beginning with the lowest which is tied fairly tightly, and proceeding to the internal ring where the last stitch is tied fairly loosely so that it will splint the conjoined tendon without putting undue strain on the muscle fibres A strip is cut from the edge of the inner flap of the external oblique aponeurosis and is left attached to the pubic bone, this is now darned loosely between the inguinal ligament and the conjoined tendon so that it is under no tension, and it remains, in fact, a graft and is *not* used as a suture The free end of this graft is then secured with a fine linen suture The floor of the inguinal canal is next inspected and particular attention is paid to the extremities The cord is allowed to fall back into position and the external oblique aponeurosis is sutured in the usual way with continuous catgut

The principal modifications of this operation from that originally described by McArthur lie in the insertion of the catgut sutures, which take up any strain to which the graft would otherwise be subjected in the postoperative period, and in the abandonment of the use of a second fascial strip to close the external oblique aponeurosis This is not necessary and only adds time to the operation, besides making larger the gap which has to be closed in the external oblique aponeurosis McLaughlin (1941) has described a similar technique, but this again uses the graft as a suture, a procedure which must vitiate a great part of its usefulness since it has been proved that a graft under tension tends to die and be absorbed instead of serving as a living framework for strong scar tissue

The postoperative regime is 14 days in bed, 7 days in the ward, 21 days sick leave and 28 days light duty Thus patients are ready for full duty in 2½ months from the time of the operation This shortened period between operation and duty is justified by the technique used, any further restriction would undoubtedly predispose to recurrence

DISCUSSION

That the technique described fulfils the principles laid down earlier in this paper is apparent The sac is removed at its highest point, the lowest part of the floor *of the inguinal canal is closed both by catgut* suture and careful fascial grafting, and firm union between the conjoined tendon and the inguinal ligament is assured by the presence of both the tension sutures, and the autogenous graft In addition the normal anatomy of the area is retained, and, if hæmostasis is secured, the result should be favourable in any given case The value of this technique must be assessed on its final results as shown by the presence or absence of recurrence, but I feel its use is justified on theoretical ground I do not assert that one standard technique should be applied to all cases of inguinal hernia, adaptability being as important in herniorrhaphy as in any other operation Nevertheless I do suggest that the operation described is the most suitable, the safest and the speediest for use in the average case of inguinal hernia as seen amongst Service personnel

SUMMARY

Of 232 cases of inguinal hernia admitted to an RAF hospital over 17 months, 77% were indirect, 12% direct, 6% recurrent and 5% associated with undescended and ectopic testicle

Principles to be observed in repair are complete dissection of the sac, proper closure of the gap between the conjoined tendon and the inguinal ligament, and special measures to secure firm union between the tendon and the ligament

A modification of the MacArthur hernioplasty, embodying these principles, is described, designed to ensure that there is no tension on fascial grafts

A postoperative regime of 21 days in hospital, 21 days sick leave, and 28 days light duty enables the man to get back to full duty in 10 weeks from admission to hospital

The method combines strong repair with relatively short incapacity

My thanks are due to the O C Hospital, and to Wing Commander J C Ainsworth Davis, for their advice and *encouragement*

CALCINOSIS CUTIS AND SCLERODERMA

THIBIERGE-WEISSENBACH SYNDROME

E W PROSSER THOMAS, M D CAMB
CHIEF ASSISTANT TO THE SKIN DEPARTMENT, ST THOMAS'S HOSPITAL

PATHOLOGICAL calcification is usually classified into two main types—metastatic and dystrophic Metastatic calcification is a rare condition in which calcium is mobilised from the normal bony storage depots and is deposited in apparently healthy tissues at various other sites It was described by Virchow in association with chronic nephritis and may occur in a number of diseases characterised by excessive bone destruction—e g , leukæmic myelosis, multiple myeloma, or carcinomatosis of bone—or it may be a result of parathyroid disease or of hypervitaminosis D The demineralisation leads to rarefaction of bone, there is generally hypercalcæmia, and the calcareous impregnation tends to occur in internal organs and viscera, such as lungs, kidneys, and stomach mucosa, as well as in the skin and subcutis In dystrophic calcification, on the other hand, lime is deposited only locally in previously dead or degenerate tissue and there is no demineralisation of the skeleton with resultant osteoporosis and no excess of calcium in the blood Necrosis and hyaline change are the chief antecedents of calcification of this common type , lime may be found, therefore, in lesions such as caseous tuberculous areas, degenerating tumours, sebaceous cysts, healed abscesses, subcutaneous veins (phleboliths) and so on

We are concerned here with another variety of pathological calcification in which calcareous infiltration occurs more or less exclusively in the skin and subcutaneous tissues This type, for which the term calcinosis is sometimes reserved, may or may not be accompanied by osteoporosis but hypercalcæmia is not constant , nor can the mechanism be explained entirely by purely local preceding tissue degeneration, although there appears to be evidence of some such preliminary change This group has been variously designated as idiopathic, primary or metabolic calcinosis Two clinical forms are often described The first is calcinosis circumscripta, affecting as a rule women in the second half of life, in which circumscribed, sometimes symmetrical but not very extensive lime deposits are laid down in and beneath the skin mainly of the upper extremities, particularly around the peripheral finger joints , it progresses slowly without serious impairment of health The second is calcinosis universalis, in which the calcium deposits are multiple and widespread, involving perhaps deeper interstitial connective tissues such as those of tendons, muscles and nerve sheaths as well as the skin , it is more commonly found in children and has a much graver prognosis Rosenberg (1940) has pointed out, however, that differentiation of these two types is applicable only to characteristic examples, many cases being indeterminate or " transitional " According to Brooks (1934) it would perhaps be more accurate to state that when calcinosis affects children the deposits tend to be more extensive and widespread, the disease more severe and the outlook more gloomy than is the case in adults

Whether calcinosis cutis constitutes a clinical entity or occurs as a " primary " affection seems open to doubt Certainly in a high proportion of recorded cases, as in the one now to be described, the cutaneous and subcutaneous calcification was but one manifestation of a systematised morbid complex

CASE-REPORT

A married woman, aged 65, first came under observation at St Thomas's Hospital in March, 1941, complaining of ulcers of arms and legs and indigestion Father died of pulmonary tuberculosis , mother of cancer of liver, aged 68 , one sister died at 40 after operation for Graves's disease , 5 siblings are alive and well , 4 children likewise Menstrual history normal The patient has never had a serious illness but ever since childhood has been subject to cold blue hands and feet during winter time and to muscular rheumatism Ulcers first appeared on the front of the legs 12 years ago and have been discharging thick whitish gritty material more or less continuously ever since About 2 years ago similar ulcers developed along the backs of the forearms and have been discharging the same type of substance For 5 or 6 years the circulation in her hands and feet has been steadily getting more troublesome and latterly has bothered her on any exposure to cold, in summer as well as winter Her fingers go dead white and are painful, turning blue as they recover Indigestion has been present for about 8 years It is getting worse and is her chief complaint There is no difficulty in swallowing but she feels all solid food sticking low down She then gets pain and regurgitates the food after a short while She does not vomit She now lives mainly on a sloppy diet For a long while she has felt easily tired but has managed to carry on a small business until a few months ago when she had to give up because of increasing general weakness For instance, she has been finding difficulty in getting her hands behind her back to do up her clothes, or in lifting herself without help, and she has to drag herself about Her muscles ache constantly

Fig 1—Left leg Calcareous infiltration of soft tissues

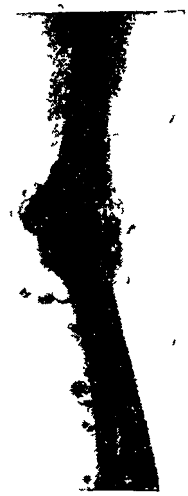

Fig 2—Forearm Subcutaneous calcium deposits mainly along ulna

A well covered woman not looking ill Face pale, smooth and rather expressionless Extensor aspects of both forearms are studded with a chain of hard fixed nodules along ulnar border from about 1 in below olecranon to same distance above wrist Some have broken down and are discharging thick whitish gritty material and resemble gouty tophi Much surrounding scar tissue Identical appearance on anterior aspects of both legs, mainly middle third, lateral to tibial crests No palpable concretions around knees or ankles In addition to scar tissue there is much surrounding dermatitis Superficial scleroderma is present over the neck, shoulders, front and back of upper chest, dorsa of hands and lower portions of forearms Distal parts of all fingers are pale, shiny, and smooth, with loss of elasticity in skin All the neck region shows diffuse brown pigmentation with depigmented waxy linear streaks along lines of cleavage Similar pigmentary changes on backs of hands and extensor surfaces of lower forearms She has noticed that her neck and hands have been getting brown lately although she is never out in the sun Numerous telangiectases are present over forehead, face, shoulders and neck, especially the V area All small, some are of " spider nævus " type fading on vitropressure, others tiny fixed red blotches A few on buccal mucosa Power in all skeletal muscles seems to be diminished, and active movements of arms, legs and trunk are restricted, although the large joints are free clinically and radiologically She cannot raise herself from a sitting position without the help of her arms Well marked Raynaud's symptoms on immersing hands in cold water Urine no abnormality BP, 170/90 mm Hg No hardening of peripheral arteries Abdomen mid-epigastric tenderness Umbilical hernia size of large plum Respiratory and central nervous systems normal Blood Wassermann and Kahn tests negative , mild iron deficiency anæmia , leucocytes, 5300 (polymorphs 45%, lymphocytes 45%, large hyalines 8%, eosinophils 1%, basophils 1%) Serum calcium (on two occasions), 8 5 mg and 8 9 mg per 100 c cm , plasma inorganic phosphorus, 4 1 mg per 100 c cm , uric acid, 2 6 mg per 100 c cm

Histology of sections of skin from sclerodermatous areas on neck and forearm (Dr W Freudenthal) —"In the bigger piece the collagen bundles, especially in a wide area in the deeper cutis, have lost their fine fibrillary structure and are caked together Although this sclerosing process has reached a high degree the elastic fibres are comparatively little altered Similar changes in a lesser degree seem to be present in the middle of the cutis of the smaller piece The histological pictures are consistent with your clinical diagnosis of scleroderma "

Radiological examination (Dr J W McLaren) —Extensive calcareous deposits are present in the soft tissues of both legs (fig 1), forearms (fig 2) and lower left thigh, the deposits being discrete and also confluent There is no evidence of any calcification in the biliary or renal areas or in any abdominal viscus The pituitary fossa is of normal size, but the calcification of the posterior clinoid processes appears to be more extensive than normal There is no evidence of decalcification in the skeletal system No substernal enlargement of the thyroid or thymic hyperplasia is shown Arthritis is present in the carpus and fingers and to a lesser extent in the tarsus and knees The affected joints show erosion of cartilage with some punched out areas and there is loss of joint space and bony rarefaction The spine shows gross osteoarthritis and the hips early osteoarthritis The œsophagus is greatly dilated but from the appearance of the film (screening was not seen) the dilatation does not seem to be due to a true achalasia of the cardia but to a spasm in the lower end of the œsophagus, the nature of which is not clear (fig 3)

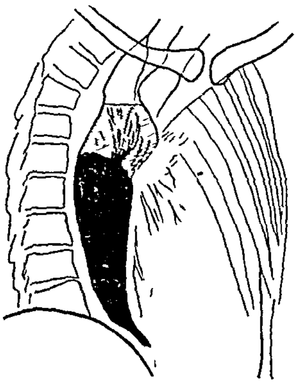

Fig 3—Tracing of radiogram of œsophagus after barium swallow Dilatation with considerable non opaque content due to retained food

Progress —The patient's dysphagia got progressively worse so that eventually she was unable to keep even fluids down She was readmitted to hospital in a very dehydrated state and died 10 days later (April 24, 1942) from bronchopneumonia During this time her blood urea was 87 mg per 100 c cm and her urine contained much albumin , urinary creatinine was estimated at 0 32 g per day and urinary creatine at 0 02 g per day (24 hour save vol 340 c cm), which amount was reported as probably not significant in view of the patient's sex.

AUTOPSY *

External appearances —Well nourished, well developed woman Calcified lumps in subcutaneous tissues of ulnar surfaces of both arms and tibial surfaces of both legs below knees Large ulcerated areas over both legs

Heart —(12¾ oz) Serofibrinous pericarditis Degeneration of atrophied myocardium Slight thickening of free edges of mitral and tricuspid valves Ante mortem thrombus filling right auricular appendage Nodule of hæmorrhage about 0 8 cm in diameter between septum primum and septum secondum of foramen ovale Patchy atheroma in coronary arteries Moderately severe general atheroma

Lungs —(R' 17½ oz , L 11 oz) Bronchopneumonia in posterior part of lower lobes of both Emphysema elsewhere

Alimentary tract —Dilatation of œsophagus up to 7 cm in diameter extending from stomach to just below level of thyroid cartilage Erosion of mucosa with much scarring at junction of stomach and œsophagus Acute ulcer (0 9 × 0 9 cm.) just distal to this, and linear erosions throughout stomach Inner lining of œsophagus covered in greater part by white shining membrane showing ill defined white lines and patches suggesting scars and dull red patch (4 × 2 5 cm) suggesting submucous hæmorrhage Slight anthracosis of lymphatics of peritoneum Multiple false diverticula of colon

Liver —(2 lb 5 oz) Severe atrophy with cough furrow in right lobe and transverse furrow in left lobe No gall-stones

Spleen —(3½ oz) Small slight hyperplasia of pulp

Kidneys —(R 4¼ oz , L 4¼ oz) Atrophied with pale cortex having interrupted pattern One large and a few small arteriosclerotic scars in cortex of left kidney Congenital cyst 2 5 cm in diameter in right

Urinary bladder —Slight hæmorrhage into submucosa and œdema of trigone

Uterus —Slight hæmorrhage into mucosa

Ovaries —Simple atrophy

Adrenals —Simple atrophy of cortex of each

Thyroid —Severe atrophy Small adenoma in left lobe

Pancreas —A few small fat necroses

Brain —(3 lb 1 oz) Simple atrophy Middle ears clean

Joints —Osteoarthritis of fingers Right knee joint large amount of brown synovial fluid , cartilage slightly brownish, surface irregular and eroded Soft red mass bulging from bodies of 7th and 8th thoracic vertebræ with destruction of body of 7th

Microscopic examination —Sections were cut of pituitary, parathyroids, adrenals, thyroid, pancreas, thoracic vertebræ, skin, œsophagus, muscle, coronary artery, lung, liver and kidney These confirmed the macroscopic findings and showed that the destruction of the body of the vertebra was due to osteitis fibrosa Calcification of the subcutaneous tissue appeared as deposits of calcium with no surrounding reaction, and apart from slight mucoid degeneration no trace of previous degeneration or necrosis

Chemical examination —The subcutaneous lumps consisted largely of calcium carbonate and to a lesser extent of calcium phosphate No trace of urates

DISCUSSION

The most striking feature of the case is the severe degree of calcinosis shown radiologically In spite, however, of the widespread calcareous infiltration which has been developing over a period of at least 12 years the patient has maintained comparatively good general health until quite recently , this is in contrast to the usual course of " calcinosis universalis " which is generally described as affecting young people and carrying a bad prognosis

Judging by the absence of skeletal demineralisation, of calcification of internal organs and of hypercalcæmia, no fundamental derangement of calcium metabolism appears to be present Normal serum-calcium levels, however, are not proof of normal metabolism without complete calcium balance studies For example, Bauer, Marble and Bennett (1931) made exhaustive studies of calcium, phosphorus, and nitrogen metabolism in a child with severe generalised calcinosis and found a well-marked tendency to retain the absorbed calcium and phosphorus in spite of normal blood levels—a tendency which was more so with calcium than phosphorus On the other hand, Brooks (1934) found pathologically high levels of serum calcium, plasma inorganic phosphorus and plasma phosphatase associated with retention of both calcium and phosphorus following probably normal absorption A disturbance in calcium and phosphorus metabolism has been indicated in other cases but in many no abnormality has been demonstrated and there is no proof that calcinosis cutis is a primary metabolic disorder analogous to uratic gout The view most generally held is that the calcification is the result of some local change in the connective tissues giving rise to a physicochemical affinity for calcium salts

Of particular interest in the present case, therefore, are the various other symptoms associated with the calcinosis—the diffuse symmetrical scleroderma with telangiectasis and pigmentation, the Raynaud's phenomena, the arthropathy, the achalasia-like lesion of the œsophagus and the myasthenia One must suspect that all these morbid processes are interrelated and that they may have a single cause

Such a line of approach has been suggested by various clinicians, notably Langmead (1923), who discussed the relationship between scleroderma, calcinosis, dermatomyositis and myositis fibrosa, and concluded that these four diseases are either all parts of one disease or that each is a clinical manifestation rather than a morbid entity He pointed out that many cases of scleroderma in which the onset was recognised and was accompanied by œdema or an eruption, and in which muscles became sclerosed, might serve equally to illustrate dermatomyositis, while some of the more chronic cases under the title of dermatomyositis are exactly comparable to others recorded as scleroderma Underlying these four disorders might be a single morbid process When it produces an acute reaction its symptoms are fever, œdema, skin lesions and myopathy, which is the picture of dermatomyositis, when the reaction is less acute sclerosis predominates over round-cell exudation and there is hardening of skin, subcutaneous tissues and muscle An obliterative arteritis would explain the commonly associated Raynaud's symptoms, and in the fibrous tissue formed in the skin or subcutaneously, and probably also in that which is perivascular, calcareous salts may be deposited and thus lead to a diagnosis of calcinosis

---

* Abstract from the records of St Thomas's Hospital medical school

In the present case it seems difficult to ascribe the calcinosis simply to a circulatory disturbance and failing local nutrition, in view of the absence of calcification in the digits, where vasospasm was so well marked, or in the areas affected by scleroderma Moreover, there was no clinical evidence either of vascular insufficiency or of scleroderma in the regions where calcinosis occurred It is also noteworthy that while the scleroderma was of a mild superficial type the calcinosis was severe and widespread Langmead's observations, however, concerning the identity of diffuse symmetrical scleroderma with dermatomyositis have been confirmed by the work of Dowling (1936, 1939), Freudenthal (1940) and Griffiths (1940), who from clinical histological and biochemical investigations conclude that these two conditions are one and the same disease involving chiefly blood-vessels, skin and skeletal muscles throughout the body In both muscle and skin the changes were considered to be degenerative and not inflammatory

Calcinosis has been observed in a number of cases of dermatomyositis and that a common pathogenic agent presumably of a toxic nature may be responsible both for diffuse scleroderma, dermatomyositis and calcinosis is shown in a case recorded by Talbott and others (1939), in which autopsy revealed, in addition to dermatomyositis, scleroderma and calcinosis, focal renal tubular infarction, obliterating endarteritis of interlobular renal arteritis, generalised arteriosclerosis and arteriolosclerosis, and central lobular necrosis of the liver

The association between calcinosis and scleroderma has, of course, been long recognised, though a group of cases was not reported until 1911 when Thibierge and Weissenbach described a patient with combined scleroderma, sclerodactylia and calcinosis, and collected 8 other cases from the literature Subsequently the syndrome has often been recorded In a tabulation of all cases of calcinosis reported up to the end of 1937—a total of 215—Atkinson and Parkes Weber (1938) note that scleroderma was present in about 36% But in 102 of the 215 cases the case-reports recorded that the calcinosis was associated with one or more of the following symptoms scleroderma, sclerodactylia, Raynaud's phenomenon, acrocyanosis, vasomotor disturbances, telangiectases, dermatomyositis and muscular wasting Such associated symptoms may also have occurred in others of these cases in mild or abortive degree or they may not have been noted or considered relevant (e g, Brooks 1934) On the other hand, when scleroderma or dermatomyositis is the main symptom calcinosis of minor degree may be overlooked unless a complete radiological examination is made

Arthropathies occur in diffuse scleroderma though they usually receive little mention in textbook accounts of the disease In 1896 Dercum emphasised that in scleroderma the disease process was not necessarily limited to the skin but might include other structures as well, such as muscles, tendons, fasciæ, bones and joints, and that the involvement of these structures might at times exceed the skin changes He noted, moreover, that bones and joints as well as muscles could be affected independently of overlying scleroderma, so that the changes in them could not be attributed to contractures and local interference with nutrition In 1898, in a paper on scleroderma and chronic rheumatoid arthritis, he cited a case in which polyarthritis of typical rheumatoid arthritis type preceded by several years the onset of diffuse generalised scleroderma with pigmentation and telangiectasia Muscles were also extensively involved, being excessively firm and hard, some of a cord-like feel He stated that repeated observations had convinced him that the conception of scleroderma, as of rheumatoid arthritis was too limited Adrian and Roederer (1920) studied the joint changes which had been described in scleroderma during the preceding 60 years and divide them into three groups: (1) joints affected primarily followed by scleroderma, (2) joints and skin affected together, (3) skin changes first and then joints They state that joint lesions in scleroderma are almost entirely confined to females and are of the polyarticular chronic rheumatoid type—not arthritis deformans According to them the process appears to originate in the synovial membrane, involving secondarily the bones and cartilages, which become the seat of rarefying changes leading to atrophy. The small joints of the hands and feet are most implicated, then the knees The arthropathy in my patient accords with this description, affecting mainly the carpus and fingers and to a lesser extent the tarsus and knees, and showing loss of joint space and erosion of cartilage

Dysphagia has often been observed in diffuse scleroderma and has as a rule been ascribed to involvement of the buccopharyngeal or œsophageal mucosa Kuré and others (1936) investigated œsophageal function radiologically in 5 cases, 2 of whom complained of dysphagia. They found in each case considerable delay in passage of the meal-mass, some of which remained stuck to the walls of the œsophagus and showed an abnormal gaping of its lumen They ascribed these disturbances to an increase in connective tissue in the œsophageal walls Weissenbach and others (1938) say that œsophageal lesions nearly always occur in the late stages of scleroderma and especially in those cases with well-marked mucosal atrophy The dysphagia, as in my patient, consists in difficulty in swallowing solid food and in a sensation of blockage, sometimes located at the upper extremity of the œsophagus, sometimes behind the sternum, and sometimes in the region of the cardia This sensation may last from a few minutes to several hours and may be associated sometimes with severe cramp-like or burning pain, often with nausea and more rarely with regurgitation True vomiting never occurs Radiologically, Weissenbach and co-workers, like Kuré and others, found in most cases morphological integrity of the œsophagus, but delay and incomplete evacuation of the opaque bolus, part of which adhered as a thin coating to the walls of the œsophagus Peristaltic contractions were almost non-existent Histologically, definite changes were observed, mostly limited to the layers subjacent to the mucosa These comprised lamellar thickening of the submucosa, degeneration of the elastic network, hypertrophy of the muscularis mucosæ and atrophy of the muscular coat

Dysphagia is also quite common in dermatomyositis and is regarded as a grave sign indicating involvement of the palatal and pharyngeal muscles It was present in 27 out of 40 cases reviewed by O'Leary and Waisman (1940) That the œsophagus itself may also be affected was shown in a case of Dowling's (1939) of scleroderma with extreme myopathy, in which radiography revealed an apparent obstruction at about the junction of the upper and middle thirds of the œsophagus for which no obvious cause was found at autopsy The X-ray appearance was ascribed to slow transit of the bolus owing to weakness of the œsophageal musculature The present case showed no buccopharyngeal atrophy and there was no involvement of the voluntary muscles of deglutition, so that the dysphagia and achalasia-like radiological appearance seem to have been due to changes in the œsophageal connective tissue or musculature or possibly both

Of the other clinical features, while telangiectasis and pigmentary changes are common in scleroderma of superficial type, in the present case the red spots and telangiectases were most numerous on the face, which apart from being rather smooth and expressionless, showed no obvious sclerosis Weissenbach and others (1938) have observed, however, that the distribution of these vascular lesions may be independent of the scleroderma Raynaud's symptoms are, of course, often present in both scleroderma and dermatomyositis Lewis (1940) says that most of the cases of scleroderma he sees are sent to him in the first instance because of these symptoms Finally, there was evidence in my patient of progressive general muscular weakness

Dowling and Griffiths (1939) point out that the occurrence of myasthenia in scleroderma seems to have been overlooked to some extent, and they have confirmed its existence in every case since they began to look for it

SUMMARY

In a woman of 65, extensive calcinosis cutis was associated with superficial diffuse symmetrical scleroderma accompanied by pigmentary changes, telangiectases, and well-marked Raynaud's phenomena Other features were an arthritis involving chiefly the carpus and fingers, an achalasia-like lesion with dilatation of the œsophagus, which was responsible for long-standing dysphagia, and general progressive muscular weakness

It is considered from the composite picture that the case belongs to the scleroderma-dermatomyositis group as studied by Dowling and co-workers

While cutaneous calcification has long been recognised in association with scleroderma (Thibierge-Weissenbach syndrome), and has also been observed in dermatomyositis, it is believed from a study of case-records of so-called primary, idiopathic or metabolic calcinosis that certain of these cases likewise were examples of the scleroderma-dermatomyositis complex, the calcification merely being part of a varied symptomatology

I am indebted to Dr G B Dowling for helpful criticism, and to Dr W I Card and Dr H Bathurst Norman for cooperation while the patient was in hospital

ABSORPTION OF SULPHANILAMIDE APPLIED LOCALLY

BLOOD LEVELS IN 41 CASES

A R HODGSON, M B EDIN J R ROBINSON, PH D CAMB
ORTHOPÆDIC REGISTRAR
NORFOLK AND NORWICH HOSPITAL

FOR some months the local application of sulphanilamide has been a part of the treatment adopted for traumatic and surgical wounds in patients in the orthopædic beds of this hospital The present work started from the observation that in some of these patients toxic symptoms occurred in the first few days of the post-operative period These included anorexia, nausea or vomiting, cyanosis, depression and prostration The cyanosis was not due to pulmonary complications The vomiting was often delayed to the second and third day, and was not considered attributable to the anæsthetic Ward sisters reported that many of these patients seemed more ill after their operations than those who underwent similar procedures before sulphanilamide was used All this suggested that the drug was being absorbed rapidly enough to reach a considerable concentration in the blood It was therefore decided to take blood from a number of patients so treated and to determine the concentrations reached

Previous workers have agreed that sulphanilamide applied locally is absorbed, but they have not agreed on the degree of absorption Jensen, Johnsrud and Nelson (1939) used local sulphanilamide in treating 39 compound fractures, and they publish blood levels from 2 of these Their figures are of the same order as ours Most of the English work has been clinical in scope and has lacked the control of blood estimations Some figures published by Hawking (1941) are much lower than the ones found here The blood concentrations in his series were rarely greater than 1 5 mg per 100 c cm The ones obtained here have usually been over 5 and sometimes over 20 mg per 100 c cm Throughout this series sulphanilamide ('Streptocide' Evans) has been used It is hoped later to publish for comparison a series using sulphathiazole, both alone and mixed with sulphanilamide

METHOD

Application of sulphanilamide to the wounds—In traumatic wounds, including compound fractures, excision of skin edges and devitalised tissue is followed by packing with a roughly measured quantity of sulphanilamide powder, worked into the crevices of the wound with the fingers Where possible primary suture follows If the wound has to be left open, 'Vaseline' gauze is used as an immediate dressing Local sulphanilamide has also been used as a precaution against sepsis in the operative wounds of a number of routine orthopædic procedures A roughly measured amount of the powder is placed in the depths of the wound After the insertion of a few deep catgut sutures, the skin edges are tightly opposed by a continuous thread suture, with the addition, where necessary, of a few tension sutures Mastisol is applied to seal the sterile dressing on to the wound When a tourniquet is used it is not removed until the wound has been closed and a pressure dressing applied When abscesses have been opened, and the wound left open for drainage, the cavity has been packed with the powder, and a vaseline gauze dressing applied

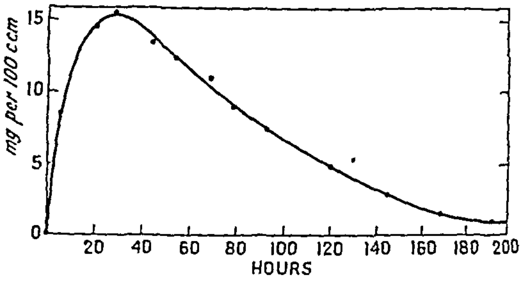

Fig 1—Case I arthrodesis of hip in man of 59 Blood concentrations reached by absorption of 15 g sulphanilamide deposited in muscles around upper end of femur

Estimation of sulphanilamide in the blood—Blood was taken from forearm veins, using a 5 c cm syringe and a hypodermic needle, and was received into tubes containing potassium oxalate After preliminary trial of several methods the one adopted is essentially that of Werner (1939)

One c cm of the blood is added in a stream to 4 c cm of 5% trichloroacetic acid in a centrifuge tube, and the mixture centrifuged, 2 c cm of the clear supernatant fluid is placed in a narrow test-tube, and there are added, first, 1 5 c cm of N/4 NaOH, and then 0 5 c cm of a 2% solution of paradimethylaminobenzaldehyde in 7% sulphuric acid A yellow colour develops It is difficult to match in a colorimeter, but as Werner points out it may be matched by solutions of potassium chromate, of which permanent colour standards may be prepared It was found possible to make the match even better under the lighting conditions used here by adding a little dichromate to the chromate To make the scale of standards, a series of solutions was first made up, containing 1, 2, 4, 6, 8, 10, 12, 14, 16, 18 and 20 mg of sulphanilamide in 100 c cm of water These were treated with the reagents to make a series of colour standards each of which was then individually matched with a separate tube of water coloured with potassium chromate and dichromate The standards were thus made by actual matching and not from Werner's table The tubes containing the chromate standards were mounted in a rack separated by a distance a little greater than the diameter of each, so that any one of the similar tubes used for the blood centrifugates could be held between any pair of adjacent tubes of the colour series Pale blue paper, illuminated by a 25 watt frosted lamp at a distance of 18 in has been used as a background

Only free sulphanilamide has been estimated, for it alone is therapeutically active, and preliminary trial showed that the method is unsatisfactory for the estimation of total sulphanilamide This and other defec re fully dealt with by Morris (1941), and in view of his survey no great accuracy can be claimed for the results But there is no point in pushing the blood estimations to a higher degree of accuracy than that with which the amount of drug placed in the wound can be gauged, and this is of necessity approximate Some is spilled, and some is often washed out by hæmorrhage The chief merit of Werner's method is its simplicity, and in view of the relatively low standard of accuracy required, and the limited time and facilities available, it was considered most suitable for the purpose

Reproducibility of results, checked by running estimations in duplicate and matching tubes in random order so that the anticipation of a result plays no part in obtaining it, suggests that between 5 and 15 mg per 100 c cm the error is of the order of ± 5% No allowance has been made for adsorption on the precipitated proteins As all specimens are treated alike, this introduces a systematic error, and the accuracy of the method is higher for comparative than for absolute measurements Standard sulphanilamide solutions made up in blood give readings a little lower than do similar solutions made up in water Consequently the figures quoted below are all probably too low by from 5 to 10%

CONCENTRATIONS REACHED IN THE BLOOD

In all the earlier cases blood specimens were taken every 6 or 8 hours for the first 24 hours, then 12 hourly, and finally daily Two typical curves are shown (figs 1 and 2) They have a characteristic shape which can easily be explained by rapid absorption and slow excretion

In the 27 cases which were followed over the peak concentration and down again, the value obtained 24 hours after operation was within 10% of the peak value except in one case, that of an arthroplasty of the hip With this same exception, the peak value was reached between 16 and 30 hours after operation In the case of the arthroplasty the blood sample taken 8 hours after operation gave the highest concentration of sulphanilamide In some of the later cases in the series only one blood sample was taken, and that 24 hours after operation

The cases are summarised in the table, which gives a short statement of the operation, with the amount of the drug placed in the wound, the concentration reached in the blood at the end of 24 hours, and short notes on toxic effects As a basis for comparison, the last column contains the ratio of the blood concentration after 24 hours to the amount of drug used—i e, the blood concentration attained per gramme of sulphanilamide used The order of cases is roughly anatomical

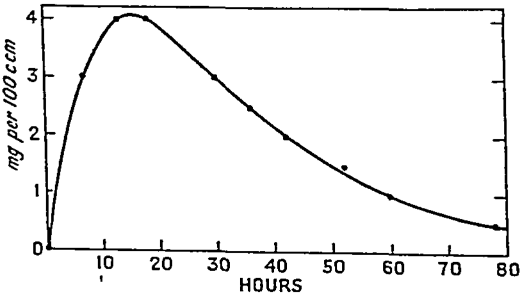

Fig 2—Case 28 compound fracture of tibia and fibula in man of 39 Blood concentrations reached by absorption of 10 g sulphanilamide deposited among injured muscles in leg

Cases 1–19 are of operations in the region of the hip and thigh

Cases 20–24 are of operations in the region of the knee

Cases 25–35 ,, ,, ,, ,, leg and foot

Cases 36 to 41 form a more mixed group

It will be seen that, when the tissue from which absorption occurs is muscle which has a good circulation, the blood concentration attained at the end of 24 hours per gramme of drug deposited in the wound is in the neighbourhood of unity In one case only, where the wound was around the hip, is the ratio as low as 0 5 This was the arthroplasty already mentioned In the course of a cup arthroplasty by the method of Smith-Petersen 12 g of sulphanilamide was buried among the muscles around the left hip-joint, 24 hours later the blood contained 6 mg per 100 c cm of sulphanilamide But the specimen raken at 8 hours contained 10 mg per 100 c cm The wound was extensive, and the dressing was soaked through, so that the low ratio is probably due partly to loss into the dressings and partly to rapid absorption giving an early peak

SUMMARY OF FINDINGS

Case	Operation	Age	Sex	(A) drug used (g)	(B) Blood concn in 24 hr (mg per 100c cm)	Toxic symptoms	B/A

SP = Smith-Petersen
V = vomiting C = cyanosis D = depression
H = hæmaturia P = prostration G, G = gas gangrene

Only in 7 cases of the 41 listed was the blood concentration at the end of 24 hours less than 0 5 mg per 100 c cm per gramme used In each case there was a reason for the poor absorption, and only these cases need separate comment

Case 28 and 29 were both of compound fractures of the tibia and fibula Muscles were severely lacerated, and in each the posterior tibial vessels were severed Circulation was impaired, and there was loss into the dressings In each, gas gangrene supervened on the fourth day, and intravenous sulphapyridine was then given as well as serum therapy In case 28 the limb had to be amputated, while in case 29 the infection was better controlled and the leg was saved

In case 33, traumatised muscle was again the tissue from which absorption occurred A gunshot wound of the foot, sustained through enemy action, caused shattering of metatarsals and much laceration of the small muscles Bone fragments were removed and the wound packed with sulphanilamide The skin was sutured As a result of trauma and destruction of vessels the circulation was reduced In addition, the peripheral site of the wound may have contributed to poor absorption

Case 17 was of an abscess in the flexor compartment of the stump of an amputation at mid thigh, carried out 7 years ago for osteomyelitis of the femur following a wound received in the war of 1914–18 The cavity was packed with 10 grammes of sulphanilamide and left open Drainage was free, and most of the drug escaped into the dressings The abscess in case 18 was an old one, with a dense fibrotic capsule, situated in the superficial fascia of the thigh The skin was sutured, so that the drug was retained, but rapid absorption was not to be expected

Absorption in cases 25 and 30 was from superficial fascia about half way down the leg In the former there was a laceration, about 7 in long, down to the deep fascia, in which the drug was placed *In the latter the site was that of a small* bone graft taken from the subcutaneous surface of the tibia

EFFECT ON HEALING AND INFECTION

While solid sulphanilamide is still present we may expect the fluids of the wound to be almost or quite saturated with the drug High concentrations in these fluids have in fact been observed by Jensen, Johnsrud and Nelson (1939) and by Hawking (1941a), who also makes the important point that the solubility of sulphonamides in water and salt solutions may give but a poor indication of their solubility in body fluids It is with this nearly saturated solution that the blood passing through the region of the wound comes more or less into equilibrium It follows that the rate of absorption should be fairly constant so long as the local solution remains practically saturated, which it does while solid remains When all the solid has disappeared, the rate of absorption should fall rapidly The significance of this is that the peak of the blood-concentration curve gives the approximate time at which solid sulphanilamide disappears from the wound This, as has been mentioned, has always been in less than 30 hours There is therefore no reason to anticipate any mechanical interference with healing from the presence of a deposit of powder This statement does not necessarily apply to other, less soluble and presumably less rapidly absorbed, sulphonamides In a few cases, some previous to the present series, wounds have been reopened 4–10 days after the first operation In no case has any trace of persisting sulphanilamide been found

We formed the impression that wounds treated thus heal a little more slowly but no less perfectly than similar wounds before sulphanilamide was used This is only an impression, the series being too short to provide evidence of statistical value The delay is certainly slight Hæmatoma formation seems more definite when sulphanilamide has been used Key and Frankel (1941) also report this Jensen, Johnsrud and Nelson suggest that it may not be undesirable The hæmatoma is a means of spreading the drug throughout the wound It is usually absorbed Sometimes a little brown fluid drains out when the sutures are removed

In no case in the series has a clean operation wound been found to be infected when exposed for removal of sutures Secondary infection after removal of sutures occurred in 3 cases

The results with infected and contaminated wounds have been satisfactory Contaminated wounds treated with sulphanilamide and primary suture usually heal by first intention Where pus has been present, it is sometimes possible to suture the skin after its evacuation and replacement by sulphanilamide, and to observe healing by first intention In granulating wounds, epithelialisation has been much more rapid than in similar wounds dressed with vaseline gauze alone

But this paper is hardly concerned with the question of whether or not the local application of sulphanilamide is sound practice in these various types of case Other series better suited to this purpose have been published The essential purpose of the *present paper is to indicate* to what extent the absorption of sulphanilamide is to be expected if it is applied locally

Before leaving the question of the control of wound infection, however, it should be emphasised that in two cases the local application of sulphanilamide, even in large amounts, failed to prevent the onset of gas gangrene In both of these cases the absorption was poor, as was the circulation in the injured tissues

SUMMARY

In 41 cases of traumatic and surgical wounds sulphanilamide has been applied locally The concentrations of the drug in the blood have been measured These have usually been of the order of 1 mg per 100 c cm for each gramme deposited in the wound In many cases local application alone will maintain an adequate therapeutic level in the blood, so that simultaneous oral administration is by no means always necessary Indeed with some wounds care is rather needed lest too much sulphanilamide be applied locally, and toxic effects result from free absorption

We wish to thank Mr G K McKee, assistant orthopædic surgeon to the hospital, for permission to publish these cases and for help in the course of the work

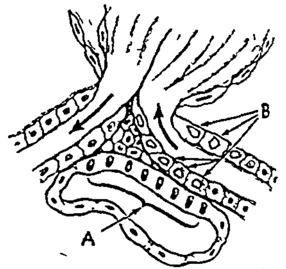
THE JUXTAGLOMERULAR COMPLEX

J F A MCMANUS, M D QUEEN'S, CANADA
CAPTAIN RCAMC
(*No 8 Canadian General Hospital, Canadian Army in England*)

THERE are an increasing number of references in the published work on experimental kidney disease and hypertension to a structure termed the "juxtaglomerular apparatus" By this term we mean a group of apparently specialised structures in relation to, and including, the afferent and efferent arterioles of the glomerulus The term "complex" is used here in preference to Goormaghtigh's term "apparatus," since he restricts the meaning to the vascular and perivascular arteriolar structures The complex consists of (1) a specialised segment of the distal, or second convoluted, tubule (A in figure) placed in relationship with the renal arterioles, in the angle formed by the afferent and efferent arterioles at the root of the glomerulus, and (2) a part of the wall of the afferent arteriole (and sometimes the wall of the efferent) in its juxtaglomerular segment, where the ordinary fibrillar muscle cells of the media are replaced by epithelial-like cells in which granules have been described (B in figure), in addition to these afibrillar cells, nervous elements are said to be present

Zimmerman[24] first recognised the different appearance of the cells of the distal tubule most closely applied to the afferent arteriole in its juxtaglomerular portion In this part, the ordinary tubular cells seem aggregated, and become in some species much higher and more columnar Because of this grouping together of nuclei, and the impression of increased density of epithelial cells produced, Zimmerman called this the macula densa He was able to find such an arrangement in all mammals examined, but was unable to identify it in the other orders of animals Since the original description, a macula densa has been found in the distal tubule in all mammals observed,[1 6 11 13] and a similar tubule-arteriole relationship has been demonstrated in bird and amphibians[2] The aggregation of nuclei is not always present in the lower orders, or even in all mammals, so that alternative terms—such as "intercalated segment" or "epithelial plaque"[2]—have been suggested, but if the limitations of the term are remembered the applied segment of the distal tubule may as well be called the macula densa as anything else



Relationships at root of glomerulus A macula densa in wall of distal tubule B, afibrillar cells, in afferent arteriole

The structure can be made out as a rule in the routine hæmatoxylin-eosin stain, but it can be seen best if the Masson or another of the trichrome stains is used, with these the distal tubule stains differently from the proximal segment and despite the severe staining procedures the macula is usually left intact although the other tubular cells are injured to varying degrees Moreover if such a stain is used it will be realised that the tubule-arteriole relationship is a constant feature of every glomerulus examined and not of only a proportion, as has been stated[2]

One wonders immediately whether the arteriole beside which the macula lies is that supplying the nephron of which the macula is a part, or whether it is some other vessel It has been assumed that [illegible] rst alternative was true,[6,7] although proof was lacking By the study of serial sections of two human cases and reconstruction it has been possible to demonstrate that the distal tubule in which the macula densa was formed was continuous with a segment of tubule which came into contact with the glomerulus According to the studies of Oliver on the plastic architecture of the kidney this is the one nephron with the glomerulus about which the distal tubule arborises

Using the Altmann-Kull technique for the demonstration of mitachondria, Ruyter in 1925 saw granular, afibrillar cells in the juxtaglomerular portion of the afferent arteriole in the mouse[19] Oberling[15] saw similar cells in the same situation in the human kidney and this has been amply confirmed[1,2,6-8,9,10,11,12] Okkels[1-18] in 1929 demonstrated granular cells in the juxtaglomerular segment in the afferent arteriole in the frog Goormaghtigh[5] described similar cells in the same situation in the cat and rabbit and later[6] noted the relationship of these cells to the macula densa Various other species have been shown to possess the granular afibrillar cells[7,13] The chief concentration of the afibrillar cells in the dog and man, where they have been most studied, is in the juxtaglomerular portion of the afferent arteriole, but they are found also in these species in the subintimal portions of the interlobular arterioles and in several sites in the walls of the smaller arterial vessels[12] Afibrillar cells in the wall of the renal arterioles have been described by many workers[20] and several have lately assumed that these are the granular cells,[2,4] without having demonstrated the granules This may lead to error no less than the contrary assumption—for example, that by which the granular cells in the frog were not recognised by the technique used[2] and were therefore said to be absent

There are some appearances in the higher mammals by which the afibrillar granular cells can be recognised tentatively without the demonstration of the granules the nucleus is somewhat distinctive showing little chromatin, a rounded outline and often a prominent nucleolus , the nucleus appears larger than its fellows and there is a clear halo in the cytoplasm immediately about it But until the main features of the granular cells can be studied with the granules visible, it seems unreasonable to attempt their recognition without demonstrating the granules, especially in an organ like the kidney, where post-mortem autolytic change is so rapid and severe

When the granules are sought, the specimen should be obtained with the animal still alive but anæsthetised , the cat shows the granules most abundantly Even here the demonstration is not easy with the described technique The Masson stain is most used for the cat, dog, rabbit and man , and Goormaghtigh who is responsible for most contributions to the study of the granular cells, has described his technique in detail[12] Even in the cat, available techniques are not consistently successful in demonstrating the granules Modifications must be attempted with individual workers developing their own technique For the cat kidney I have used with success a preliminary deep staining with eosin (0 5% aqueous eosin for 5 min and the section decolorised to deep pink with tap water) followed by the usual Masson stain Goormaghtigh is also responsible for pointing out the existence of nerve-fibres and cells in intimate association with them Edwards[2] has confirmed this in several species and some incomplete work of my own seemed to show nerve-fibres in and about the terminal portion of the afferent arteriole in the dog kidney

REACTIONS OF THE JUXTAGLOMERULAR COMPLEX

The first description of an experimental alteration of the juxtaglomerular complex was that of Elaut,[3] who described hyperplasia of the afibrillar cells in animals made hypertensive by nerve section or carotid sinus techniques It is interesting in the light of later work that these changes were interpreted as an attempt at decreasing the shock of the raised blood-pressure striking the glomerulus Goormaghtigh in 1937 described selective damage to the fibrillar muscle cells, with sparing of the afibrillar granular cells, in 4 fatal cases of scarlet fever With Handovsky he later described similar selective damage from large doses of vitamin D in the dog Animals with hypertension showed an increase in the granular cells, sometimes at the expense of the fibrillar myocytes, from which they seemed in some instances to be formed It was suggested that these cells elaborated the pressor substance, and this view was supported by the finding that rabbits made hypertensive by the Drury technique showed hyperplasia of the afibrillar cells in the ischæmic kidney[8] , this has been confirmed by Dunihue and his associates[1] The ischæmic kidney of the Goldblatt dog showed also hyperplasia of the afibrillar cells[10] and on these data Goormaghtigh elaborated his theory of the endocrine nature of the afibrillar granular cells of the juxtaglomerular apparatus[11,12] Under the same conditions which produced these changes in the afibrillar cells, the macula densa was seen to undergo changes of a degenerative, vacuolar type

Since the description by Goormaghtigh concerning the complex in scarlet fever, there has been no published description of pathological reactions in the human kidney from this viewpoint Preliminary studies of my own appeared to show involvement of varying degree in some 30 cases of glomerolonephritis, with the greatest alterations in those cases which had, during their terminal illness, the least range of concentrating power Since, however, lesions in nephritis are inconsistent, these incomplete studies can be considered as no more than suggestive In the human kidney it was noticeable that one element of the complex—the macula densa or the afibrillar cells—rarely seemed to be affected without some change affecting the whole complex Thus in the more extreme cases the arteriolar wall was hyaline, the macula was swollen and hardly recognisable and there was, in addition, some hyaline connective tissue between the vessel and the tubule More careful studies may demonstrate lesions of one part of the complex, but the grosser affections of the complex alter all its parts It was this joint reaction of the arteriolar and tubular portions in man, and the similar joint action in the animal experiments described by Goormaghtigh, that suggested the term " complex " to signify the integral nature of the unit

ENDOCRINE ACTIVITY OF THE AFIBRILLAR CELL

The cycle of activity which Goormaghtigh has described for granules of the afibrillar cell[12] seem to indicate an endocrine nature, as he suggests Direct repetition of his work has not been forthcoming, and one must seek elsewhere for additional evidence Friedman and Kaplan[4] have shown that renin[21] can be extracted from the glomerular kidneys of the carp and dogfish but not from the aglomerular kidney of the midshipman fish The carp and dogfish are described as having aggregations of cells at the glomerular root resembling the juxtaglomerular apparatus These workers conclude that renin must exist in the glomerulus or glomerular arterioles and not in the tubules as Weeks[2-] has suggested This seems to be locating the hypertensive substance very close to the juxtaglomerular complex.

A second suggestive though indirect lead is furnished by the descriptions and illustrations by Weiss and Parker[23] of the entity which they term hyperplastic arteriolosclerosis , they saw this in their cases of pyelonephritis and glomerulonephritis and only in those which showed hypertension Histologically, it was characterised by cellular overgrowth of the intima of the small renal arterioles , and the picture described is in keeping with that which would be produced by hyperplasia of the afibrillar granular cells in these smaller vessels The evidence so far available to suggest the afibrillar cells as the site of the elaboration of the pressor substance is certainly not extensive , but what evidence there is does indicate how confirmation of Goormaghtigh's theory would help to settle some of the problems of kidney diseases

FURTHER LINES OF RESEARCH

Demonstration of the granules in the afibrillar cells is difficult The granules have been seen and photographed, so that their existence need not be denied , but newer staining techniques must be developed Each worker must develop a suitable means for making visible the granules of the animal used in experiment

Research on the juxtaglomerular complex need not be concerned with hypertension alone In the frog there is a well-developed complex with both the granular cells and the tubule-arteriole relationship represented Some experiments of the type of made by Richards might determine the condition in the distal tubule, whether chemical or hydrostatic, which affects the flow through the glomerulus Okkels[16] has shown already that it is at the site of the granular cells in the frog kidney that the afferent arteriole responds to mechanical stimulation by closing off the blood-flow through the glomerulus Comparative review of the known renal functions in the different orders of animals in which the juxtaglomerular complex has been described suggested to me that the complex was not concerned with the excretion of urea, uric acid, chlorides, sugar or non-protein nitrogen nor with the volume or dilution of the urine The common factor seemed to be the intermittency of flow of blood through the glomerulus, and it is possible that this is controlled, or regulated, by the juxtaglomerular complex

The reactions of the complex in human nephritis, no less than in the several experimental forms, will be of interest It may be necessary to cast off some of the terminologies which encrust the study of the kidneys, especially their pathology but pathological changes in the kidney will only make sense to the clinician when they can be interpreted in terms of functional change, and the most promising suggestion of such a possibility is found in the juxtaglomerular complex Kaufman[14] has lately described hyperplasia of the afibrillar cells in human cases of kidney disease associated with hypertension This seems like a start along one of the most hopeful lines for further research

SUMMARY

The juxtaglomerular complex is a group of apparently specialised structures in relation to, and including, the afferent and efferent arterioles of the glomerulus In the vessels, the ordinary fibrillar cells are replaced by afibrillar cells in which granules have been demonstrated in some species The afibrillar cells occur in the interlobular arterioles in some of the higher mammals A segment of the distal tubule of the same nephron as the glomerulus is placed close to the afferent and efferent arterioles and often there is a change in the character of the tubular cells adjacent to the afferent arteriole Nerve cells and fibres have been described with the vascular and tubular elements and there is some evidence to suggest that the intermittent blood-flow through the glomerulus is controlled or regulated by the juxtaglomerular complex

In experimental hypertension produced by renal ischæmia in the dog and rabbit Goormaghtigh and others have described hyperplasia of the afibrillar cells of the renal arterioles and this has been seen also in hypertension produced by carotid sinus techniques as well as hypervitaminosis D in the dog Recent work has strengthened Goormaghtigh's suggestion that the afibrillar cells produce a pressor substance, inasmuch as renin can be obtained from the glomerular kidney of the carp and dogfish but not from the aglomerular kidney of the midshipman fish In man, the process of hyperplastic arteriosclerosis, described by Weiss and Parker as being seen only in hypertension, would result from a hyperplasia of the afibrillar cells in the interlobular arterioles

The original work described in this paper was begun while assistant resident pathologist to the Johns Hopkins Hospital, and continued while resident pathologist to the New York Hospital, Cornell University Medical School Parts have been included in papers presented to the Ontario Association of Pathologists, 1940, and the Canadian Physiological Society, 1940, as well as to the Royal Society of Canada at the 1941 meeting

POTENTIALITIES OF MUNICIPAL MEDICINE*

H JOULES, M D LOND, M R C P
MEDICAL SUPT OF CENTRAL MIDDLESEX COUNTY HOSPITAL

AN account of the development within the municipal hospitals under the most progressive authorities during the past twenty years would constitute a record of achievement unequalled in any hospitals previously As an example twenty years ago the titles of the wards of the Central Middlesex County Hospital were

1 Nursery	4 Female Workhouse
2 Aged Female Block	5 Female Feeble minded Ward
3 Female Infirm Ward	6 Female Insane Ward

These had their counter-parts on the male side One doctor acting as medical supt and master, served their needs Today this is an acute general hospital of almost 1000 beds with an admission-rate of 10,000 per annum and an outpatient department with over 100,000 yearly attendances A complete list of facilities now available would fill pages, but the following selection will indicate the increasing specialised services

1 A maternity block of 60 beds with antenatal and gynæcological wards of 50 beds, associated with appropriate outpatient departments

2 A dietetic department of 50 beds, a dietitian, special kitchen and outpatient department at which a chiropodist attends

3 A neuropsychiatrical department of 50 beds, associated with a mental observation unit of 16 beds with appropriate outpatient facilities

4 Two wards to which all cases of acute respiratory infection in adults are admitted for special investigation and treatment

5 A pædiatric department and outpatient facilities with cots for the admission of 100 children, but not fully occupied owing to war conditions

6 A neurosurgical department dealing with the major neurosurgery of the county

7 A genito urinary surgical ward and outpatient department

8 A tuberculosis department of 35 beds

9 A pathological department, staffed by two whole time pathologists and many technicians, with which is associated a medical artist †

10 A treatment centre for venereal disease, open daily

These departments are in the charge of members of the whole-time clinical staff, while certain other specialised work is dealt with by visiting consultants—e g , dermatologist, ophthalmologist, oto-rhino-laryngologist and physiotherapist A radiologist attends daily on a sessional basis The other large general hospitals administered by the county have developed along somewhat similar lines, dependant on the needs of the population served

Much discussion within the hospital and elsewhere has centred round the position of the medical superintendent, that bogy-man who is often said to be the complete bar to any reasonable hospital service In this hospital, with its weekly general medical staff meetings and monthly senior staff meetings, we try to discuss hospital problems and development in a spirit of cooperative helpfulness We are hopeful, too, that before long further modifications in the superintendent-clinician relationship will be officially recognised and that a more liberal administrative machinery will extend throughout the whole hospital

The possibilities for specialisation are thus increasing for all members of the senior staff, while a perspective is maintained by undertaking a share of the acute general work, medical and surgical, of the hospital Almost weekly meetings of the clinical and pathological staff have been a feature for several years now, while frequent, well-attended demonstrations to the practitioners of the area have been held

---

* Based on the chairman s address to the Middlesex County Medical Society, Sept 11 1942 † See *Lancet*, Sept 12 1942 p 325

Much remains to be done particularly in respect to increased staffing, both medical and nursing , a recognition must come too, of the need for more than one senior physician surgeon and obstetrician in a hospital of this size Criticism is often levelled at our improving services on the score that nothing comes out of them, especially in medical literature The most important product is the ever-increasing stream of well-treated patients which should be the first criterion of a hospital s efficiency With increasing opportunities, increasingly valuable contributions to medical knowledge will be forthcoming

THE FUTURE

We have already in Middlesex specialist chest and neurological surgeons who are responsible for most of the surgery undertaken in these specialties Radium and X-ray therapy are centralised in one hospital Further developments along these lines must be encouraged The suggested formation of a clinical research society to work within the county hospitals opens up a vista of immense importance With effort and goodwill throughout research questions can be dealt with on a broad basis and on a wealth of clinical material which has not been collectively available anywhere in this country previously

Contact between the general hospitals, sanatoria and mental hospitals the county medical officer of health his assistants tuberculosis officers and those engaged in school maternity and child-welfare work, should be increased for therein lies the basis for the furtherance of true social medicine The establishment of chairs of social medicine in university centres is a necessary step but it would be deplorable if from the first we allowed this idea to pass into an academic retirement from which it might never emerge The place in which social medicine must flourish is within such an integrated service as we hope our county service is tending to become Problems needing solution will arise both centrally and peripherally, and it should be the function of our central organisation, working with the clinical research committees and all necessary medical auxiliaries, such as health visitors almoners and technicians, to find the answer to disease incidence throughout the county Often it will be found that social and working conditions are responsible for much that is preventable and it should be the duty of our public health administration so to stress these facts to the administrative body that preventive action must be taken Close association between hospitals, public health workers and the health centres in which practitioners will work, should be instituted as soon as the latter are established In this way we can rapidly form a body of health workers deriving strength from our unity

The facilities for both undergraduate and postgraduate teaching within such a scheme should be apparent Health problems of the whole area will be within its purview and it should be possible so to organise a clinical course that students do not get the impression that medicine consists of equipping oneself to undertake major operations on the thyroid gland or the stomach, or learning all about rare diseases to the neglect of the first principles of healthy living

Postgraduate lecture demonstrations both to and by our practitioners should be a regular procedure Education of the public in healthy living should go hand in hand with the increasing integration of the health service Encouragement should be given to the public to play its part in instituting healthy conditions both in their homes and their places of work A scientifically controlled health propaganda will not result in a morbid public

" Doctors forget the roots of disease which are often to be found in social conditions , they say that that is a matter for the medical officer of health Students are trained to deal with diseases but are not trained to look into conditions which prevail in factory and in the homes the conditions under which illnesses have arisen ' So said a member of Parliament in a recent debate Municipal medicine should have every incentive and facility to reverse this just accusation

Many of us will have been amused by the assertions of eminent authorities, who have never held whole-time posts, that a whole-time service such as ours prevents our appreciating the sacred doctor-patient relationship and that patients do not like " municipal robots " I am convinced of the falsity of this view Our daily contact with patients in the ward, as senior clinicians brings an intimacy and understanding which cannot be attained in a somewhat pontifical weekly teaching round A salaried medical service under a local authority such as ours has advantages which far outweigh any temporary loss of social prestige

---

ADVANTAGES OF A SOCIALISED MEDICAL SERVICE *

SOMERVILLE HASTINGS, M S LOND, F R C S

THE state has provided a series of watertight compartments for the treatment of some diseases (tuberculosis, venereal diseases, cancer), and this has been arranged for the most part without any cooperation with the general practitioner who must inevitably first see the cases No scheme can be complete unless it includes the general practitioner, on whom must always depend the early and correct diagnosis of any case as well as its direction to the appropriate place for treatment

An extreme, but by no means unique, example of incoordination in health services is to be found in the facilities available for the mothers of London, who may be delivered by a LCC midwife or in the wards of a LCC general hospital ; by a borough council midwife or in the wards of a borough council maternity hospital (in some boroughs) , in the maternity ward of a voluntary general hospital or by a midwife attached to that hospital , by a maternity charity (either in hospital or by midwife) , by a midwife in private practice , or by a private doctor who may be doing much midwifery in a busy practice or be attending to but two or three maternity cases a year

The first necessity for an efficient health service is unification of existing agencies under a real Ministry of Health, which would be concerned exclusively with health matters in every department of state This ministry would of course have the duty of enforcing on local authorities the decisions of Parliament For efficient health administration the local authorities must themselves be large—much larger than most of those existing The country might be divided up into a dozen or more areas of administration each to consist of one or more counties with included county boroughs It would be best for each of these areas to be controlled by a popularly elected body which would deal not only with health but other local government activities as well On the health committee there should be room for the cooption of doctors and others who have made a study of health problems or had experience of health administration The final decision on all questions must however, be made by the consumer that is by the elected representatives of the people who must consequently be in a majority on all the main committees Some experience of health administration has convinced me that there are many intelligent laymen and women who have a much greater insight into health questions than many doctors would give them credit for

Though the administrative region for health services should be a large one, for practical working it should be subdivided into divisions of such a size that all the doctors in each, both general practitioners and specialists, should know each other and get used to working together The ideal unit or division might have a population of about 100 000 , and *the simplest unit to consider* is a small country town with the surrounding country district This would need a hospital of about 1000 beds near the traffic centre for almost every type of case, and the specialists attached to this hospital would also be available to see patients in consultation with the general practitioners or home doctors at the health centres or in their homes It will probably be convenient to have the main divisional health centre in close association with the divisional hospital, and here perhaps most of the cases referred by the home doctors will be seen by the specialists There will also be local health centres in urban and rural districts

Reviews of Books

Basic Concepts in Social Case Work

Herbert H Aptekar Chapel Hill University of North Carolina Press London Humphrey Milford, Oxford University Press Pp 201 *15s 6d*

This book could only have been written in America It illustrates the new trends and conceptions which are fundamental to good case work Those who recognise the value of psychiatric social work in this country will welcome a book analysing lines of progress in selected cases To many the social worker is still someone who gets something done—signs a form, arranges convalescence, finds a new house—much as a stenographer types a letter But the situation in which one person seeks help of a material kind from another is far more complex than this The extent to which the experienced social worker holds back from making up the client's mind may come as a surprise to those who are accustomed to her active and practical rôle Nor has she any fixed approach , the relationship is essentially a changing and a growing one The social worker " presents to the client the means for a partial or temporary solution and requires that she make a decision on this point The contact resolves itself into a kind of experiment in living, based upon the client's desire for, and the agency's ability to offer, a particular service " The phrase " an experiment in living " should go far to dispel the picture of the social worker as a kindly middle-aged woman arranging the lives of the poor Here, the newer conception has come to take its place in the regimentation of life necessary in time of war, and it can and should be used fully There is some irritating distortion of terminology in the book The terms are carefully defined, and follow the usage of Rank and the Pennsylvania School of Social Work, but psychiatric terminology is sufficiently complex without the use of personal interpretations of standard terms such as " projection " Occasionally the language is needlessly obscure, but incidental flaws should not dissuade the reader from a careful study of this newer dynamic case work

Schizophrenia

R S Ellery, MD, FRACP, psychiatrist to the Alfred Hospital, Sydney Sydney Australasian Medical Publishing Co Pp 170 *12s 6d*

An exuberant straining after fine writing and a rather clamant political outlook are what distinguish this book from many others which set forth what is known and what is guessed about schizophrenia Dr Ellery is convinced that environmental factors are of the first importance in the causation, and therefore also in the prophylaxis, of this illness " those who see man from the dialectic angle as an integral part of his environment believe that only through the operation of profound changes in this environment can a true prophylactic programme be achieved They hold that cultural forces may be more potent than biological tendencies, that economic pressure and social custom may be stronger than the ' diversity of genes ' said to be responsible for constitutional characteristics " Whatever may be thought about the dialectical angle of vision, the argument presented for this recurrent theme of the book is too deductive one would prefer more evidence and less assurance

The book is well produced and anything but dryasdust, beginners would find it stimulating but sweeping and not always trustworthy

The Medical Annual

Editors H Letheby Tidy, DM Oxfd, FRCP, A Rendle Short, MD Lond FRCS Bristol John Wright and Sons Pp 396 *25s*

This year the familiar annual is a little smaller, but perhaps not altogether the worse for that Contents, paper and illustrations, all are well up to the old standard The comprehensive subtitle—" a year book of treatment and practitioner's index "—lays on the editor a heavy task of selection, and the result is no chance collection of abstracts but articles from some 35 experts on their subject Many bear a direct relation to war medicine—for example, the pages on shelter hygiene by Lord Horder, on mass radiography of the chest by W E Lloyd, burns by C P Wakeley, war wounds by L Rogers and the sulphonamides by R Heathcoate The several hundred articles, long and short, are with few exceptions concisely and clearly written

The annual is essentially for those who want practical guidance but the research worker need not despise it References to original papers are numerous and there are 25 fine plates

Recent Advances in Obstetrics and Gynæcology

(5th ed) Aleck W Bourne, MB Camb, FRCS, FRCOG, Leslie W Williams, MD, MS Lond, FRCS, FRCOG London J and A Churchill Pp 363 *18s*

The style of this short readable book is more virile than that of previous editions Only those recent advances worthy of comment and assessment are included , thus three chapters found in the previous edition have been omitted and a much needed chapter on postnatal care has been introduced In discussing habitual abortion the authors rightly recommend progesterone, but propose that its injection should be continued to the 26th week of pregnancy, though there seems to be no evidence to warrant its continuance after the 14th week Nor is it clear that vitamin E—which is also recommended—has any influence on human abortion A plea that more general use of episiotomy in labours where the head is slow to emerge would help to abolish functional prolapse is perhaps rather a dangerous incitement to the surgically minded obstetrician , it is not desirable that episiotomy should become a routine manœuvre In the chapter on anæsthesia too little emphasis is laid on the need for adequate trained nursing care of the patient under twilight sleep Steele's technique for the use of ' Pentothal ' is not mentioned in discussing the use of the barbiturates during the first stage, and no mention is made of vinyl ether or cyclopropane for the end of the second stage, though either is to be preferred to ether or chloroform In the gynæcological section the chapters on carcinoma of the cervix epitomise the best teaching in British surgery sterility, leucorrhœa, sympathectomy, the sex hormones and ovarian tumours are particularly well discussed The book as a whole will be welcome to everyone interested in gynæcology and obstetrics

Diseases of the Blood and Atlas of Hematology

(2nd ed) Roy R Kracke, MD, professor of bacteriology, pathology and laboratory diagnosis, Emory University School of Medicine, Ga , U S A London J B Lippincott Co Pp 692 + xxx, 54 plates *£4 10s*

This revision of a standard American textbook is uneven The sections dealing with the white blood cells are first-class, the illustrations equal to anything yet produced, with specially good plates showing the odd types of leucocytes in glandular fever, and the various myeloblasts in acute leukæmia The section on leukæmia by Lloyd F Craver is complete and up-to the minute, even mentioning the therapeutic use of radioactive phosphorus compounds and the method of total body irradiation for lymphatic leukæmia Other good sections deal with malarial parasites, hæmoglobinuria, children's anæmias, and the blood pictures of common laboratory animals F P Parker contributes a comprehensive section on blood-groups and blood-transfusion But a new section on hæmoglobin and its derivatives is marred by the absence of illustrative formulæ, and the work of Fairley on methæmalbumin is not mentioned

Useful smaller sections deal with such matters as the differential platelet count, and hæmophilia and its inheritance and the value of globulin fractions in treatment , a frank table puts in their place the various liver extracts available on the American market The section on technique is complete and straightforward In the sections on anæmias and the morphology of the erythroblasts the author seems to be confused by the various terminologies, and it is strange that no coloured plate should show the changes in the sternal marrow smears induced by liver treatment in pernicious anæmia—one of the most informative demonstrations in hæmatology But the book will certainly find its way into our libraries if only for the excellent leucocyte plates

THE LANCET

LONDON SATURDAY, OCTOBER 3, 1942

RUSSIAN VICTORIES IN SOCIAL MEDICINE

IN 1920 Dr L Haden Guest, accompanying a British Labour delegation, gave a picture in our columns[1] of social conditions in the USSR and of the immense task then facing Prof NICOLAI SEMASKO, the people's commissar of public health The Czarist regime had left a grievous legacy and the political upheavals which followed the revolution had made it impossible to get supplies of even such elementary public health equipment as dressings and soap Quinine was so scarce that there was hardly any in the whole Volga region, and there were only 17,000 doctors for a population of 125 million, their work had to be supplemented by that of 35,000 partly qualified medical assistants and 120,000 juniors presumably equivalent to clinical clerks and dressers In the eight months before July, 1919, 1,299,262 cases of typhus were registered, with a death-rate of 8–10% In Astrakhan during the same year there were 600 cases of cholera and mild amœbic dysentery, and on June 7, 1920, when Dr Haden Guest was there, about 70% of the populace had malaria (no quinine) and the hospitals contained 642 cases of scurvy, 14 of typhoid, 306 of relapsing fever, 6 of smallpox and 196 of typhus Typical syphilis rates at that time were 156 per 10,000 in Petrograd and 123 in Olonets, Professor SEMASKO agreed that 80% was a fair estimate of the incidence of "custom syphilis" found in some South Russian and Ukrainian villages This was due largely to the traditional customs of kissing at Easter, kissing the ikon, feeding babies on chewed bread and using a common cup Now, after twenty-two years, Professor SEMASKO is able to look back on his remarkable handiwork He does so too modestly in an article lately received by the Anglo-Soviet Medical Council

The chief weapon against social diseases has been the dispensary Russian dispensaries differ from those elsewhere in being completely organised for prophylaxis as well as therapy They provide free medical service, but also supervise measures to suppress disease and prevent its propagation Thus the staff of an anti-tuberculosis dispensary treat the patients, inspect their living conditions, ensure proper nutrition, and send those who need it to hospitals and sanatoriums, they also inspect the families of patients, especially the children, and fortify them against infection as well as they can by improving their health The result has been that in Moscow and other large cities tuberculosis decreased by more than half between 1926 and 1937 The anti-venereal disease dispensary must not only give free treatment but track down the source of infection, and treat the responsible patient If necessary, treatment can be made compulsory Doctors and nurses pay home visits if need be to ensure regular treatment Thanks to the treatment of pregnant women, congenital syphilis is now rare Prostitution has disappeared with the ending of unemployment—its main cause—but years ago the dispensaries had to work with the police to stamp out centres of prostitution Women were placed in prophylactoriums under supervision and were taught socially useful work, while receiving whatever treatment was necessary Many of them later became well adjusted and were able to take a normal place in society The number of such institutions has steadily decreased and recently they have hardly been needed though two or three were still maintained before the war Custom syphilis has vanished with the harmful customs which caused it, and in Moscow primary syphilis is so rare that the professors have difficulty—as they do here—in finding cases for demonstration to students

Housing had been improving steadily up to the outbreak of war, both in town and country districts Hours of work had been shortened and regular rests and holidays had been ensured The health of the people had further benefited from safety devices and cleanliness in factories, and the standard of living had risen very much Tuberculosis as an occupational disease has been disappearing as a result The marriage-rate in 1938 was 5% higher than in 1937, and divorces had fallen by 47% as compared with those of 1936 The law passed in 1936 prohibiting abortions also provided every kind of assistance to parents in bringing up their children, as well as new creches, kindergartens, and children's homes

German invasion of Russian territory has brought the usual ills of war in its train Women have been violated, brothels opened, and hospitals and prophylactic centres destroyed But in unoccupied districts the work goes on as before, and the medical services to the Forces are in themselves a great achievement

PLANNED NUTRITION

THREE centuries ago THOMAS MOFFETT advised that diet, though called a frivolous knowledge by the impudent and a curious science by the imprudent, should be embraced "as the leader to perfit health and a sound body" The impudent and imprudent are still to be found, even in our profession there are faddists of the back-to-Nature breed who would have us subsist on berries, there are scientists in arm-chairs who would have us eat rotted liquid herrings because laboratory analyses show them in that state to contain more nutriment The nutrition of the body cells, on which the nutrition of the population ultimately depends, may falter, rarely, through an insufficient supply of oxygen or inadequate removal of waste products, it suffers commonly through failure to ingest the right foods, because of ignorance of what the right foods are, unsound cooking that makes them unappetising and destroys essential nutrients, or most likely because the right foods are unavailable for economic or other reasons A successful food policy must therefore ensure that the existing supplies of food are available and that they meet the nutritional requirements of the people The first is broadly the concern of the Ministry of Food, the second of the Ministry of Health Lord WOOLTON has made a fine job of making the food from our farms and from abroad available to 47,500,000 people each day, in the face of demands for economy in shipping-space and the dispositions of U-boats But can we agree with his statement made a year ago that there is no sign of malnutrition in Britain ?

[1] *Lancet*, 1920, ii, 518, 566, 617

It is only in the last few years that methods have been devised for assessing the nutriture of samples of the population The Ministry of Health was slow to adopt those methods and until recently relied on the reports of its medical officers of health and the results of the clinical assessment (or "glance method ") of the Board of Education—a method now largely discredited Sir WILSON JAMESON, however, has been quick to apply the newer knowledge of nutrition A year ago he defined the necessary technique as a combination of dietary survey, laboratory control and clinical examination[1], at the beginning of this year he announced that such surveys were being made by the Ministry, and their value has been stressed by Prof J C DRUMMOND[2] Dietary surveys, though they have played an honourable rôle in the past and will continue to be useful for limited purposes, are now having premortal paroxysms (" one can hardly take a mouthful without someone wanting to weigh it ") Most of their results are of relatively trivial value, for the method teems with inaccuracies owing to insufficient data on analyses of foods, losses in cooking and plate-waste The relative value of laboratory control and of a clinical examination can best be appreciated by recalling the sequence of events in the development *of nutritional deficiency in man* The ingestion of food inadequate in a specific nutrient, whether or not detectable by the dietist, usually leads to a fall in the concentration of that nutrient in the blood That fall may be detected by biochemical methods before any *ill health occurs* The fall continues and when the function of certain cells becomes impaired there is vague ill health with decreased efficiency, both bodily and mental, this may be detectable by physiological methods, such as the measurement of dark-adaptation Later—usually much later—the earliest structural changes occur and can be detected by refined clinical methods, terminally a disease such as scurvy appears We can therefore apply to the population filters of graded pores for sifting the malnourished from the fit The finest filter is the analysis of the blood, the coarsest is the diagnosis of textbook deficiency diseases (rickets, scurvy, xerophthalmia, beriberi, famine œdema) But blood analyses are difficult—even hæmoglobin estimations are not straightforward The intermediate grade of *refined clinical methods provides a sieve of treacherous* value, for the early signs and symptoms are unspecific —follicular hyperkeratosis is not always or even often due to deficiency of vitamin A, nor gingivitis to deficiency of vitamin C The slit-lamp microscope is a great help, but if the sweeping claims are correct that KRUSE[3] makes for its use in diagnosing deficiency of vitamin A by examining the conjunctivæ, of vitamin C by examining the gums[4] and of nicotinic acid by examining the tongue,[5] then we are almost all deficient and someone should start a crusade in quest of the normal man These methods, biochemical and clinical, having been used throughout the population, critical evaluation and supervision must be applied to them By the results of such critical surveys, existing nutritional deficiencies and downward *nutritional* trends can be discovered, ill health anticipated, and the food situation remedied That is medicine—preventive medicine The diagnosis concerns the Ministry of Health, the therapy the Ministry of Food But those are not the only official bodies interested The cooperation of the Ministry of Agriculture is essential, and the Board of Education is clearly concerned There are problems of transport, of commerce and above all of economics, for food merely rots if the people cannot afford to buy it And there are problems of education, to teach the people the right foods and the right ways of preparing them The problems, therefore, though primarily medical, stretch wide, and need a central organisation —a Nutrition Council—to control them

There is no existing organisation that can coordinate all these varied interests The Medical Research Council has done admirable pioneer work in the field of nutrition, particularly animal nutrition Its Committee on Human Nutrition, which last met a few years ago, before the war, would doubtless be strongly represented on such a council So would the Armed Forces, and in that way greater efficiency would be produced by coordinating research (recently the possibility of a particular vitamin deficiency occurring in the Forces was investigated by each of the three independently and differently without any collaboration) Other countries have set up such councils For instance, the Canadian Council on Nutrition is a voluntary advisory body formed in 1938 with the deputy minister of pensions and national health as chairman, its executive committee consists of the five members of the subcommittee on nutrition of the *Dominion Council of Health, and of the nine* members of the scientific advisory committee of the Dominion Council of Health, and it has 32 additional council members Further, it incorporates the central federal office for nutritional work, which is called Nutrition Services, and is deeply concerned with education in food matters Such a Nutrition Council should be official, but only its executive committee should be concerned with policy and should therefore include representatives of the Armed Forces, the other council members should coordinate and advise The final report of the mixed committee on nutrition of the League of Nations called attention in times of peace to the wide prevalence of malnutrition, and pointed out that the movement towards better nutrition had been largely the result of the unconscious and instinctive groping of men for *a better and more* abundant life, what is required is the conscious direction of the natural tendency towards better nutrition Such direction constitutes policy which requires the guidance of some central authority The committee said " We are more than ever convinced of the necessity for bringing together scientists, economists, agricultural experts, consumers' representatives, teachers and administrators in National Nutrition Committees It is our firm belief that through National Committees the most useful progress can be made One of the most important tasks is to ascertain the prevailing food-consumption habits and nutritional status of all sections of the population " If the need for such a council existed in peace, it is more dire now If it existed in 1937, when methods of assessing nutrition were scanty, it is greater now when such methods have been elaborated and refined If it existed when nations were isolated, it is vaster now when the nutrition councils of the United Nations could work together in feeding their peoples during the war the

tricken peoples in the famines after it A new desire o join forces has infiltrated nutritional scientists but hey must perforce work alone without knowledge of what others are doing, even the ministries are out of contact with much of the work Now is the time when all bodies interested in nutrition should be coordinated with the Ministry of Health, through a Nutrition Council, to abolish unnecessary duplication, prevent confusing statements being issued to the public and further a national nutrition programme that will ripen to an international food policy

MEDICAL HAZARDS OF AIR TRANSPORT

REPORTS from the Libyan campaigns show that as air superiority was gained, air transport for the wounded came to be more often employed Little has been made public about the indications, or what is more important the contra-indications for such transport out there LOVELACE,[1] of the Mayo Clinic where a special aviation laboratory has been established, has assessed some of the contra-indications He points out that in the normal person anoxæmia begins and oxygen administration becomes necessary at about 10 000 feet In the anæmic patient the effects of oxygen want will be felt at lower altitudes, for there is less hæmoglobin available to carry the oxygen The anæmic patient should therefore have oxygen administered in flight even at low altitudes He considers high altitude flight in the pneumothorax case particularly dangerous He reminds us of Boyle's law, whereby if the temperature remains constant the volume occupied by a given sample of gas is inversely proportional to the absolute pressure under which it is held Thus with ascent, as the atmospheric pressure falls the volume occupied by a pneumothorax increases, and at a little over 15,000 feet is actually doubled—even at 10,000 feet there is an increase of 1 5 times in volume Air transport of the closed pneumothorax—whether artificial, spontaneous or traumatic—is therefore risky, and may result in respiratory embarrassment and rupture of pleural adhesions The deep-sea fish, with his closed swimming bladder never ventures far up into shallow waters LOVELACE and HINSHAW[2] have shown that the onset of unpleasant symptoms is to some extent governed by such factors as fixities of the mediastinum, thickness of the visceral pleura and the degree of the negative intrapleural pressure at the start of the ascent This specialised aspect of the subject is not so important in war as it will be afterwards when commercial air travel is likely to assume a larger place in our lives

The air of mediastinal and subcutaneous emphysema is subject to similar pressure changes, and LOVELACE considers that the same physical principles apply to the volume of gas in the stomach and intestines and, in the case of the wounded, that with ascent the recently sutured bowel may be blown and leak In intestinal obstruction this increased distension may be disastrous He suggests that in such cases it will be of advantage to maintain continuous suction by means of a duodenal tube, or perhaps even better a Miller-Abbott tube In cases of cerebral injury or laceration he quotes evidence to show that oxygen is early needed, and that with ascent there is an increase in intracranial pressure An experiment in support of this contention was done by WALSH,[3] on a woman of 35, who had had a temporal decompression for focal encephalitis diagnosed in error as a cerebral tumour A small metal mast was fixed with some collodion to the scalp over the defect and its movements recorded with the patient in a low-pressure chamber Atmospheric pressure was reduced to imitate an ascent to 28,000 feet The mast pointer rose 1 cm, and the scalp, formerly depressed, now bulged out WALSH and BOOTHBY have also shown that on ascent to 28,000 feet intraspinal fluid pressure on lumbar puncture rises 30 mm of water The reason for this increase in intracranial tension is not yet determined, and WALSH points out that it may be due to expansion of air in the ventricles, or to alteration in the blood circulation or the amount of cerebrospinal fluid

It is of course unlikely that altitudes of 28,000 feet will be used for the air transport of wounded But JESSE WRIGHT[4] of the United States Navy hopes it will be possible to provide some special ambulance planes with sealed cabins to maintain atmospheric pressures near those of sea level The Germans have been aware of these hazards, and HIPPKE,[5] their chief of air medical services, reports that during the Polish campaign the pilots of the air ambulances were instructed not to fly higher than 3000 feet As far back as 1937 the Germans were transporting wounded of the condor legion from Spain via Italy by air The weather was not so favourable there as in the bright summer of the Polish campaign It was found that local ground visibility and choppy weather made rapid ascents to 12,000–15,000 feet essential, and this has to be borne in mind in assessing transport risk In the Polish campaign HIPPKE reports that 2500 sick and wounded were carried, and he says that although prolapse or pressure symptoms are theoretically to be expected in cerebral or abdominal gunshot wounds they met with none, he considers that plasters and covering dressings may be sufficient to prevent them He is not sure about thoracic injuries, and some of the patients did die en route Shock, "inclination to shock," and severe anæmia he regards as the only contra-indications to air travel He says that the Germans intended to develop as an air ambulance the Fieseler-Storch plane which starts and lands easily in small fields A large plane needs a large landing field, and much of the value of air travel is likely to be lost in the long ambulance journey required to reach it

TUBERCULOSIS IN SWEDEN —After a period of regression between the two wars the number of tuberculosis cases in Sweden is once more increasing and the health authorities have launched a nation wide anti-tuberculosis *campaign* Mass radiography of large population groups and BCG vaccination are the foremost measures suggested In the first place everyone who has to do with children, passenger traffic and foodstuffs, should be subject to these precautions which would later be extended to women and adolescents in industry Between April and June this year 85,000 officers and soldiers of the Swedish defence forces were X rayed, and, so far, 15,000 soldiers have been BCG vaccinated The Swedish National Anti-Tuberculosis Union has also started an examination of the people in the northern parts of the country where tuberculosis is common The examination is done in a specially constructed X ray bus, where up to 100 people can be examined in an hour

Annotations

DIAGNOSIS OF BREAST TUMOURS

THE wealth of pathological material received for diagnosis at the Royal College of Physicians in Edinburgh provides an opportunity for checking diagnostic methods The service has already been used for the benefit of systematic pathology in a series of articles on debatable *tumours in human and animal pathology*[1] A further contribution has now been made by Dawson and Harvey[2] with the object of correlating the macroscopic and microscopic diagnosis of mammary cancer The results of the two methods of observation are in such close agreement that they suggest a practical application to war time conditions War of necessity reduces peace-time standards not only of living in general but of medical practice also Pathological services, like all others, are working with reduced personnel and materials There appears to be justification in the results recorded for sacrificing much time consuming microscopic technique in favour of macroscopic diagnosis Of 95 cases in which radical and modified radical mastectomy was performed, the macroscopic diagnosis was correct in 94, of 35 cases of simple mastectomy, diagnosis was correct in all 35, of 79 local excisions or biopsies 73 were correctly labelled, and of 48 doubtful cases only 4 were incorrectly diagnosed It appears from the first two sets of figures that not only were the pathologists almost always right but the surgeons also, for the correct method of dealing with the tumour had been chosen at operation It looks as though the surgeon should only send for microscopy those breast tumours about which he is doubtful

THE THREE-IN-ONE DOCTOR

IN a recent issue of the *National Insurance Gazette* the story is told of a member of an approved society who believed himself to be suffering from an industrial disease, and went to be examined by the certifying surgeon, " only to find that that gentleman was his own panel doctor and also the works doctor " The man was certified in March of this year as suffering from myocardial degeneration In May he went into a hospital, and when his wife visited him she noted that his chart was marked " Lead normal " This being reported to the man's society, it was ascertained that he had been employed for a number of years as a maintenance fitter in a red lead plant The man was then advised to see the certifying surgeon who issued a certificate to the effect that he was not suffering from lead poisoning (" He could hardly, as panel doctor, give a certificate for myocardial degeneration, and as certifying surgeon give one of lead poisoning ") Next the man applied for examination by a medical referee, who certified him to be suffering from lead poisoning, and back dated the certificate to the first day of incapacity His employers then sent him to be examined by a specialist, who turned out to be the doctor who had been in charge of his case at the hospital The story concludes " Had the member's wife not seen the wording on the hospital chart and had she not made a report to us, the member would have gone on being certified as suffering from myocardial degeneration But what is the position of a medical man who is panel doctor plus works doctor plus certifying surgeon? And does he at any particular time serve the interests of the patient or the employers or act as an independent representative of the state?" The obvious moral of the story is the ease with which a case note can mislead an anxious relative and the significance of a diagnosis elude an earnest official The " lead " of an electrocardiogram unfortunately has the same spelling as " lead," the metal In any case it is possible for a patient with lead poisoning to have myocardial degeneration as well But the real moral lies deeper It is surely all to the patient's good to have the same doctor supervising him at home and at his work, and it seems the ideal solution to combine in one person the panel doctor, the works medical officer and the examining surgeon This would obviously simplify the difficulties discussed on p 405 But the man's union sometimes fears that a doctor paid by a firm would be prejudiced against the workers This is not the experience of those who know the high standard of fairness and impartiality shown by works medical officers and examining surgeons If their decisions can be said to have a bias, it is on the side of the workers—which seems natural enough in a profession whose training and experience give them a high sense of human values The doctor patient relationship is something apart It may be that the individual worker is more conscious of this than those who represent him

BIRMINGHAM BROADSIDE

IN a clear and soberly written little book prepared for the Birmingham Social Survey Committee (*Nutrition and Size of Family* Allen and Unwin 2s 6d) Mrs M S Soutar, Dr E H Wilkins and Prof P Sargant Florence present, somewhat belatedly perhaps, the results of an investigation into food expenditure carried out during April–August, 1939 The inquiry was limited to families with one or more children living on a new housing estate (Kingstanding) about 5 miles from the centre of Birmingham Information was collected from 269 families, the object being to ascertain the extent of poverty in families and the comparative conditions of life in families of different sizes No attempt was made to inquire into the composition of family diets—always a difficult matter when housewives have to purchase in pennyworths and consumption is often straight out of the paper bag

The degree of sufficiency of income was determined in two ways (1) by comparing net income (i e, total income less rent, compulsory insurances and fares to and from work) with an assumed minimum standard of expenditure on food, fuel, light, clothing and cleaning materials, and (2) by comparing with a minimum standard of expenditure on food the *balance out of housekeeping money theoretically available for food,* after paying the assumed minimum on non food items in (1) plus voluntary insurances and regular hire purchase instalments In the first approach—which we should today describe as the unrealistic method—the minimum diets set up by the BMA in 1933 were used Diet No 2 (repriced to 7s 8d for an adult male) was used without alteration and for other expenditure the standards set up by the Bristol Survey[1] were closely followed The application of this conventional approach showed that 14% of the total families on the estate were on the borderline or below sufficiency Of the families studied the proportion in each group on or below the " needs " standard were with one child 3%, with two children 11%, with three 27%, with four 55%, with five 60%, and with six or more 82% This is indeed a relentless gradation even on a standard which allows an inadequate quantity of milk, fails to recognise the protein needs of adolescents, disregards the needs of heavy workers, ignores illness and rests on the assumptions that furniture costs nothing and lasts for ever, that no one pays voluntary insurance or doctor's bills, or spends anything on holidays, recreation or amusement, and that all the people concerned are non smokers, teetotallers and do not read newspapers

But the promoters of the survey were not satisfied, they realised that they were dealing *with human beings,* so they set out to ascertain the amount which the bread

1 Harvey, W F, Dawson, E K and Innes, J R M *Edinb med J* 1938, 45

2 Dawson, E K and Harvey, W F *Ibid,* 1942, 49, 401

1 The Standard of Living in Bristol Preliminary report of the work of the University of Bristol Social Survey, B 1938,

winner gave the housewife as housekeeping money and they then compared the cost of the standard minimum diet with the money apparently available for food It is in this section that the book is most original and valuable The results of the method showed that 31% of the total families on the estate were below sufficiency Of the families studied the proportion in each group below sufficiency were with one child 13%, with two children 45%, with three 65%, with four 85%, with five 96%, and with six or more 96% Ascertainment of the proportion of all the 8150 children on the estate inadequately provided for disclosed that 31% were on or below the borderline of sufficiency by the first measure and 60% below by the second and more realistic measure Actual poverty, as shown by the housekeeping balance available for food per man, is much greater than that shown by the type of measurement usually adopted in social surveys The investigation illustrates, as the York, Bristol, Liverpool, Sheffield, London and other surveys have done, the financial inability of many working class families to maintain for their children a standard of living compatible with full growth and health What is particularly significant about this survey is that it relates to a "prosperous" period, there was very little unemployment, overtime was common and "most of the gardens are well kept, the hedges neatly trimmed, and there is a general external air of prosperity"

Apart from the original things this book has to say on gardens, parlour type houses, purchasing habits, irregularity of income, the burden of hire purchase and voluntary insurance payments (past insecurity and future uncertainty) there is one important message—in which the hand of the late Dr M'Gonigle can be seen—for those concerned with planning the postwar world All the families on the estate had been rehoused and this involved an all-round increase in the cost of living, significantly, the proportion of bread in the diet rose after rehousing It is clear that as an independent social reform rehousing has its limitations It may be ungrateful to ask for more from the authors of such an excellent and understanding piece of work but we should like to know how the conditions of today compare with those of the summer of 1939

SUDDEN DEATH IN INFANCY

WHEN an infant who seemed well is found dead in its cot or pram it is natural to presume that it has been suffocated by its bedding or has died of foul play Thelin[1] has urged that the conclusion should not be drawn hastily—never on external findings alone and only with great care after autopsy From the scanty published work on the subject we know that "acute suffocating catarrh"[2] or "acute bronchiolitis"[3] may commonly cause unexpected death in infants, and, what is more important, may run the most fulminating course to end fatally in as little as 12–18 hours,[4] during the early part of which nothing untoward is noticed A child may seem normal to its mother when fed and placed in its bed or pram, only to die asphyxiated in its own inflammatory bronchial fluids during the quiet breathing of sleep when the cough reflex is dulled and secretions accumulate A vicious circle is set up, in which congestion and œdema and even acute congestive bleeding into the lung take place, completing the closure of the air-passages Convulsive movements of anoxic kind may disturb the bedding or turn the child over, and some mechanical interference with breathing may follow With these several factors operating together difference of opinion as to the precise causation of death may arise Thélin, from a somewhat confined experience of 30 cases in the medico-legal institute of Zurich, claims to have dissipated all suspicion of accident or foul play by finding inflammatory secretions causing asphyxia in no less than 20 and a large thymus (with the conventional apologia) in a further 3, leaving only 7, say one out of every four, in which asphyxia from external causes, suffocation by bedding or foul play was responsible for death Unfortunately Thelin shows a serious disregard for microscopy and histological confirmation of the nature of the process Experience of asphyxia autopsies quickly teaches one that never with the eye alone is it safe to judge the nature of the process which fills the airways and precipitates death, never, unless frank yellow pus is present, is it safe and proper to attribute death to natural causes The bronchial fluid must be microscoped, nothing can take the place of this essential scientific proof, and without it we must still form the view, however unwelcome, that accident in the bed, the bedding or the nightclothes was responsible For proof of a criminal act we must have, in addition, some well defined marks to show its nature, without these we may have our suspicions but we cannot act This distinction between natural disease and accident is a matter only of care and patience, caution in microscopy of fluids would be likely nearly to reverse Thelin's figures His remark that his figures represent "the view of all those who have occupied themselves with the problem" is unfounded, it does not represent English experience

SPITTING AND EXPECTORANTS

THE facility with which the lung absorbs fluids presumably has some influence on the amount of sputum coughed up, and hence a bearing on the action of expectorants Basch, Holinger and Poncher[1] have observed the physical and chemical properties of sputum in two patients with bronchiectasis Specimens of sputum were obtained by bronchoscopic suction and the observations included estimations of the organic and inorganic contents of the samples and the viscosity of the sputum They distinguished three different types of sputum in the bronchial tracts of these patients (not to be confused with the three layers into which bronchiectatic sputum separates on standing) The first type is a bronchial mucus plug, rarely seen because often lost during the cough, with a high viscosity and low content of organic and inorganic material The second type occupies the trachea and larger bronchi, and is subject to considerable fluctuations in viscosity and content of solid matter, it derives from the third type of sputum, which, lying in the most dependent part of the lung, is very viscous with a high content of organic and inorganic substances, this is never coughed up but is liable to ascend to the larger bronchi as a result of such forces as the tussive squeeze Basch and his colleagues conclude that the differing viscosities of the sputum depend on reactive processes within the bronchi, and that changes resulting in dilution may take place by the secretion of liquid substances into the sputum, by resorption of solid substances from the sputum or by bacterial or enzymatic liquefaction The traditional use of expectorants is based on the assumption that these drugs liquefy the secretion and hasten resolution by facilitating absorption at the alveolar surface The limited amount of experimental work on this subject has been reviewed by Alstead[2] By measuring the daily output of sputum during a control period and after the administration of expectorants, he was unable to confirm the orthodox view that these drugs increase the output of secretion Basch and his colleagues reject the method of measuring and weighing expectorated sputum, partly because they consider it inaccurate and also because it does not take

[2] Alstead S *Lancet* 1941, i, 308

into account the possibility of resorption of sputum under the influence of expectorants From their own observations on sputum, collected under supervision or by bronchoscopic suction, they conclude that expectorants given "at regular intervals day and night in the usual dosage" do lower the viscosity of the sputum Their results must be discounted to some extent, however, because in about two thirds of their experiments figures for viscosity are either omitted or show differences which having regard to the method employed are probably not significant Viscosity charts covering a period of two or three weeks would have been preferable to single readings, since it is essential to obtain some idea of the spontaneous variations found in the course of an exacerbation of bronchitis untreated by expectorants If the fluctuations are as great as those in the volume of the daily output of sputum a liberal allowance must be made before alterations in viscosity are attributed to expectorant drugs or other measures Basch and his colleagues report favourable results from ammonium chloride, potassium iodide, senega and ipecacuanha, and steam inhalations were even more effective than expectorant drugs Inhalations of carbon dioxide lowered the viscosity of the sputum considerably Oxygen had the opposite effect, but with mixtures of the two the action of CO_2 predominated They therefore regard CO_2 as an expectorant because it liquefies the sputum, stimulates the cough reflex and favours resorption Research on expectorants in the human subject might profitably combine serial observations on the viscosity and the daily output of sputum That it is possible to affect the volume of the pulmonary secretion by pilocarpine and atropine is beyond dispute but these drugs are practically useless in the treatment of bronchitis on account of their intolerable side effects Nor are drugs that have a beneficial action in the bronchial tract when given in dosage provoking nausea likely to find favour among patients The point in dispute is whether non-nauseating doses of the expectorants, given —as they usually are—when the stomach is full of food, can cause liquefaction of the sputum If liquefaction of the sputum and diminishing viscosity can be effected by these drugs in spite of a downward trend in the daily output of secretion then we must revise our definition of the term "expectorant" Otherwise the student will be asking "when is an expectorant not an expectorant?"

A GREAT ENCYCLOPÆDIST

J P writes Carl Oppenheimer was a remarkable man springing from a remarkable family When Chief-Rabbi Oppenheimer of the Oranienburger Synagogue in Berlin gathered his family on a Friday evening for the sabbath supper, there would be Franz, the eldest, the famous professor of economics Paula, the elder daughter who was famed for her fairy tales and children's books, with her husband Richard Dehmel, a Poet Laureate of Germany Then the younger daughter with her husband Steindorf, the celebrated Egyptologist, and lastly the Benjamin of the family Carl, biochemist and medical author Carl Oppenheimer's name is not connected with any great research or invention, his talent lay in compilation he was a medical chemical encyclopædist of the highest rank His little book *Ferments and their Actions* published in 1905, developed into the *Handbuch*, known to all biochemists, which will remain a standard work He was able to simplify even such complicated studies as Wieland's dehydrogenation theory and Warburg's theory of oxidation by catalysis, and he brought order into the bewildering nomenclature and classification of enzymes He published accounts of the development of this specialised branch of knowledge in *Enzymologia*, and, not content with this gigantic task, undertook in 1909 to edit the *Handbuch der Biochemie*, which he completed in two years, later he prepared new editions as they were needed He also edited the *Zentralblatt fur Biochemie und Biophysik*, the *Tabulæ biologicæ* and the *Tabula biologica periodica* His interest was by no means confined to biology, few textbooks have had a popularity comparable to that of his *Textbook of Organic and Inorganic Chemistry*, which ran into 15 editions Yet he did not seek a serious environment I don't think any social club could have been more gay, more sparkling with wit and laughter than the laboratory of our great teacher N Zuntz, where I was fortunate enough to be associated with Oppenheimer, Neuberg, Cronheim, Caspari and L Michaelis A Durig and others Oppenheimer had a happy disposition, he was a keen mountaineer and motorist, a good companion and a self sacrificing friend Born in Berlin in 1874, he lived in exile in Holland the last years of his life, heart-broken, and ill with a slowly developing malady, but thinking about the future with his friend and publisher W Junk He is mourned by two sons, of whom the elder is chief of the experimental botanical garden of Rehovot in Palestine

HOSPITAL SURVEYS

FOR some months Dr A M H Gray and Dr A Topping have been surveying the facilities and gaps of the hospital services of London Mr E Rock Carling and Dr T S McIntosh have been doing the same for the North-West of England and North Wales, and last week Prof J A Ryle and Dr A E Quine began work on the North-West of England Speaking at Oxford on Sept 25, the Minister of Health announced that the Nuffield Trust had now appointed Mr H L Eason, MS (chairman of the GMC) Dr R Veitch Clark (former MOH for Manchester) and Mr W H Harper (house governor of Wolverhampton Royal Hospital) to undertake the three ridings of Yorkshire, and he expects further extensions of this orderly network before long The first function of the surveys, Mr Brown continued was to find out the facts, then second to give opinions and advice founded on these facts As far as publication went he distinguished sharply between these two kinds of material Facts should of course be made freely available to all, but he was quite sure that the reports themselves must remain confidential to the trust and to his department if they were to be full and frank They would inevitably lose in value if they were prepared as public documents From a study of the facts and advice tendered by the surveyors he would in due course draw his own conclusions, and the facts and these conclusions would be laid before the local authorities and governing bodies of voluntary hospitals But there would be no question of imposing a ready made plan or of requiring local action to be taken in accordance with these conclusions Legislation would probably be necessary later to give effect to the Government's declared policy of laying on the major local authorities, in full consultation with the voluntary bodies concerned, the duty to provide an adequate hospital service But this legislation would be the subject of consultation with all interested parties before it was introduced into Parliament and Mr Brown envisaged that it would embody the normal procedure of calling for proposals from the local authorities in each area In drawing up their proposals the local authorities and the voluntary hospitals could only be helped by the spade work covered by the surveys and the recommendations based on them Thus the object of the surveys was not to produce working drawings but to provide "a rich fund of knowledge and experience on which those may draw freely who are charged with the task of producing working drawings"

ON Monday, Oct 19, at 2 30 PM SIR WILSON JAMESON, will deliver the Harveian oration at the Royal College of Physicians His subject will be war and the advancement of social science

Special Articles

TIME AND THE SECOND MB

REFLEXIONS ON THE STUDENTS' GUIDE

SAMSON WRIGHT, M D, F R C P
OHN ASTOR PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON, MIDDLESEX HOSPITAL MEDICAL SCHOOL

THE medical course is already extremely long—in the pinion of some, too long Medical knowledge is still dvancing rapidly and will no doubt advance rapidly for many years to come If we attempt to teach students ll that is known it would take them a life-time to master their subject It is the business of the teacher, after the appropriate time to be devoted to any particular part of the curriculum has been decided, to select from his subject those aspects which are of greatest value to the future practitioner and which also serve in training the student in the methods of science It is his business also to see that no more is attempted in the time than a man of average intelligence can satisfactorily master

I want to apply these general principles to the 2nd MB course in the University of London Unfortunately the student at present working for this examination believes that he is studying at least a dozen subjects dissecting-room anatomy, embryology radiological anatomy surface anatomy (in some departments, I think, " living anatomy "), histology, physiology, organic chemistry, biochemistry, experimental physiology (in some places biophysics), neurology, special senses, pharmacology, and so on and so forth In point of fact he is simply studying the arrangement, structure and workings of the body particularly the human body The arrangement of the body is studied in the dissecting-room on the surface in the living subject and in the X-ray room Structure is dealt with in histology and the rest of the student's time is, or should be devoted to various aspects of function Forty years ago our knowledge of function was much more meagre than it is today, though our knowledge of arrangement and structure was almost as complete , then it was reasonable and natural that most of the student's time should be devoted to arrangement and structure, and a small part only to function Today the situation is reversed far more is known and will be known about function than ever will be known about arrangement and structure From the point of view of the practitioner functional problems are becoming increasingly important Allocation of time suitable forty years ago is entirely unsuitable today

How much time should reasonably be allotted today to dissecting-room anatomy ? Practical anatomy manuals employed by most students are not student textbooks but encyclopædias Present-day anatomists, in fact if not in theory, demand that the student should dissect in the greatest detail every part of the body and master most of the details Anatomists say that all they require of students is the fundamentals of the subject , and this may be true as far as heads of departments are concerned But the student is guided by his textbooks and by demonstrators in the department who are often working for the higher surgical examinations and are deeply interested in the minutiæ of anatomy Students believe they have to master practically all that is known about topographical anatomy I suggest that our first step should be to reduce the amount of time spent in the dissecting-room to not more than 25% of the total time in the curriculum One distinguished professor of anatomy tells me that in a course of 40 weeks total duration an average of 6 hours a week for dissecting should be adequate (total 240 hours) In London the terms are longer, and on an average the student is spending 32 hours a week at the school for not less than 50 weeks and in some places 60 weeks at 8 hours anatomy a week the total available is say 400–480 hours If to this figure of 8 hours a week for dissecting another 2 hours are added for embryology histology, surface anatomy, radiological anatomy, and any other methods that may be available for studying arrangement and structure, a total of 500–600 hours are provided which seems quite adequate I am not suggesting that in a course of 10 hours a week the student could master all the anatomical detail that he studies, and that is actually expected of him now The course will have to be revised so that inessentials are eliminated, and only such facts taught as are necessary for the training of the general practitioner Any student who wished to become a surgeon would return to his anatomy later to master the degree of detail necessary for his future work

My suggestion would leave about 20 hours a week available for the study of function Many anatomists are uninterested in the teaching of topographical anatomy, many have taken over histology but do not find that satisfying either, and are not happy even when they give an elaborate course in embryology Many are anxious and some are competent to teach function There is, however, no reason for calling the functional aspects " anatomy " Most anatomists like to teach the physiology of bone, many like to talk about growth, and some are interested in reproduction, some in neurophysiology , there may be anatomists who would like to teach hæmodynamics There is no harm in anatomists desiring to teach function provided they are clear in their minds that hæmodynamics, for instance, or the physiology of the nervous system, really are aspects of function, and do not deal primarily with considerations of arrangement and structure Each medical school must decide for itself which members of its staff are most competent to teach the various branches of the curriculum If it was thought that a professor of anatomy should teach the physiology of the nervous system, he could teach it in the laboratory in the school equipped for the purpose At present many departments want to expand, and they assess their importance by the number of hours of the student's time that they can claim and the number of teaching laboratories under their control Subdivision of the curriculum for the 2nd MB into watertight compartments is an increasingly antiquated system which will soon have to be modified The teachers concerned with function ought to confer, and select from the immense mass of material at their disposal those aspects of the subject which will enable the future practitioner to do his work efficiently and also make him a man of science

The teaching and examination in organic and biochemistry are under discussion Medical students are not being trained to become organic chemists they need a knowledge of fundamental organic chemistry in order to understand the chemical processes taking place in the body in health and disease The course in organic chemistry in most medical schools would equally well introduce any branch of organic chemistry , it is not specifically directed to the purposes of medicine. The preparations and tests that the student carries out have no intrinsic, and little educational, value He has learned to weigh and measure and carry out simple calculations in his inorganic chemistry course and he will get further practice in the course for the biochemistry section of the 2nd MB What he clearly needs is a combined course which should be called what it is—biochemistry This should teach him the fundamentals of chemistry in so far as they are needed for his biochemistry, and he will then proceed at once to study biochemistry both theoretically and practically Such a coordinated course would be more useful, enabling him to deal much more thoroughly and in as short a time, with the chemical processes in the body

---

THE DOCTOR IN THE FACTORY

A MEMORANDUM[1] on medical supervision in factories, issued by the Factory Department sets out on broad lines the duties which a medical officer may reasonably be expected to fulfil He must have direct personal contact with the management, so that any views he expresses will be immediately and sympathetically received The department thinks it better still if he is an integral part of the management on the personal side, though he should not be concerned with wages, hours of work or conduct of the factory on the production side except so far as hours and conduct of the factory affect the health of the worker It is a weakness of the industrial medical service that there are workers who feel the doctor is the servant of the management, chiefly interested in maintaining production The implications of this paragraph in the memo are very wide

---

[1] Form 327 H M Stationery Office Pp 8 2d

The principal duties of the medical officer, as set out here, are to organise first-aid treatment for injury and sickness in the factory and to help in ARP services and training, to examine and advise those referred to him by the labour manager, those who wish to consult him, and those engaged in work with special hazards, to make sure of the fitness of those returning to work after illness, to advise the management on general hygiene and educate the workers in general and personal hygiene, to cooperate with the management and outside welfare authorities on all matters affecting the health of the people, and to maintain an effective liaison with private practitioners, hospitals and local authorities, and to keep confidential and adequate records Medical examination of new employees is not required by statute except for those under 16 or those about to be employed in special processes, but the memo suggests that medical examination of all entrants should now be considered Those employed in specified processes which carry risks have to be examined at regular intervals, and with the approval of the Chief Inspector of Factories the works medical officer can undertake such examinations Apart from this, a large labour turnover or a falling off in production by a given group may lead the medical officer to examine that group with a view to finding out whether the nature or conditions of work are responsible, and if so whether any preventive measures could be introduced By keeping in close touch with private doctors the medical officer can give much useful advice about the return of a man to work after illness The private doctor may hesitate to send a patient back early because he knows nothing about the kind of work he will be expected to do, or he may unwittingly sign the man off before he is fit for his particular job If the factory and the private doctor work together it should always be possible to get the man back to his job as soon as he is fit, or to put him temporarily on to some suitable employment until he has recovered his full powers This degree of cooperation between factory and private doctors has not yet been achieved, as was evident from discussion at the BMA annual representative meeting[2]

It is also the task of the works medical officer to help in the rehabilitation of the injured workman by arranging graduated work for him, and in collaboration with the tuberculosis officer to devise conditions of work suitable for a man returning from sanatorium treatment In order to judge of the strenuousness of different types of work the doctor must be familiar with all the processes in the factory, this will also enable him to recommend improvements in working conditions It is not his primary duty to undertake any treatment other than first-aid, but if further treatment can be conveniently given at the factory the memo suggests that it should be considered, provided the private doctor agrees In that case the factory doctor would send full details of the treatment given to the private doctor, or to the hospital if the man had been attending there He would also let the doctor or the hospital almoner know if the firm was willing to help the man to get special or convalescent treatment If the patient was referred to a physiotherapy centre the factory doctor would keep in touch with his progress there and encourage him to attend regularly The medical records should be confidential and the doctor should have charge of them, this would not preclude him from sending a report on general lines to the management about the health of the workers, attendances at the ambulance room, absences for illness, or excessive sickness-rate among groups of workers There should be some attempt to make records uniform, and the memo suggests a form of record card which might be used in factories Workers can be taught principles of general and personal hygiene in talks to individuals or groups of workers, The memo insists that the medical officer must have a consulting-room of his own

Much of his success will depend on establishing cordial relations with the workers, to this end (if to no other) he is advised to take an interest in social life and recreations in the factory

PALESTINE

TUBERCULOSIS

THE Hadassah University Hospital has published a review of the findings of various workers from which it appears that in many European countries the mortality from tuberculosis is lower among Jews than other people, while the incidence is higher This apparent paradox is ascribed to the poor conditions and the crowded quarters of towns in which many Jews live, they are thus freely exposed to infection, and the incidence is therefore high, but they also become immune to acute rapidly fatal forms of the disease In Tel-Aviv, which has the largest Jewish population in Palestine, between 1938 and 1941 the mortality from tuberculosis was about 3 8% of all deaths—a low figure, corresponding to about 0 3 per thousand population in the town The rate in Jerusalem was about the same The Jewish league for the control of tuberculosis in Palestine has increased its membership to 5500 and extended its activities to 12 new subdistricts In the spring a propaganda week was held with lectures and meetings at which the work of the league was described In this war as in others the incidence of tuberculosis is increasing and more patients are needing hospital treatment Beds are scarce, however, and other measures have to be resorted to, thus the University Hospital at Jerusaleum has appointed a physician to spend his whole time in visiting small country district where the incidence of tuberculosis is high He examines the entire population and gives theoretical and practical advice on the treatment of tuberculosis to local doctors and nurses The league maintains a convalescent home for tuberculous patients

FLOWERS ON THE ROCK

At the University Hospital in Jerusalem a new garden of the Mediterranean type has been planted for the pleasure of patients and visitors This may not sound much of an achievement, but Mount Scopus, where the hospital stands, is rocky and almost bare of any green plants The new garden has thus been won at the expense of a determined struggle, and will be appreciated in proportion

INSULIN PRODUCTION

The shortage of insulin noted in earlier letters[1] has by now been largely overcome Dr Geiger of Jerusalem has been working for the past ten months on the preparation of insulin, and by the end of February was ready to undertake large-scale production of the hormone in the crystalline form Local animal material is sufficient to provide insulin for all the diabetics in Palestine, and the home-made supply will mean saving in shipping space

FLUKE INFESTATION

Dr A Bychovsky reports 50 cases of infestation with *Heterophyes heterophyes* seen during the past four years This small fluke measures 1–1·7 mm long and is a fairly common parasite in Egypt, China and Japan It inhabits the small intestine, and when the flukes are present in large numbers may cause a catarrhal state with diarrhœa Bychovsky's patients complained in addition of pains in the abdomen, nausea, a bad taste in the mouth and lack of appetite Eosinophilia was sometimes present The infection was acquired by eating those species of fish which are intermediate hosts for the cercaria Of his series of 50 patients, 44 were women, he explains this as being due to a housewifely custom of tasting the fish before cooking it Treatment was by anthelmintics, especially thymol in doses of 0 5 g three times daily for 4 or 5 days

MEASLES PROPHYLAXIS —The results of prophylactic injection of convalescent serum in a group of 84 child measles contacts are reported by L de C Freire and J Cutilhero (*Amatus Lusitanus*, 1941, 1, 207) The injection was given from one to twelve days after exposure In 3 cases prodromal symptoms were already present, and in them the injection was without effect Of the remaining 81, only 3 had an ordinary attack of measles, 11 had mild, attenuated attacks and the rest escaped altogether These observers maintain that convalescent serum is much more effective than either adult whole blood or placental extract

In England Now

A Running Commentary by Peripatetic Correspondents

THE average city dweller is not greatly given to looking at the sky in times of peace. It is true that the suburban resident has a habit of glancing skywards as he says good-bye to his wife on the doorstep of a morning. But at the best it is but a perfunctory business, for if it looks like rain he takes his umbrella as a matter of course, and if it does not look like rain he takes it as a precaution. In war-time we all see much more of the sky. Sudden noises make us look skywards by day, and long nights on the roof make heavenly bodies imminent and even friendly. Many urban dwellers must be familiar with such things as Orion's belt that they had been accustomed to think were only revealed on dreamily romantic summer nights during the annual holiday at the sea-side. There are more than stars to be seen by gazing at the sky, and there are more occasions for gazing at the sky than those provided by the alarms of aerial warfare. The other day I visited my dentist in a horrible industrial city of the North West. As I lay, gagged, in his chair one piece of blue was all that I could see through the upper panes of his window. Into this patch of blue there floated the quite unmistakable, wide-pinioned form of a buzzard. Round and round in wide circles the beautiful thing passed slowly across my patch of blue. By making signs and inarticulate noises I attracted the dentist's attention to it and before it had drifted beyond the frame of the window we had both seen what I expect no other person in that city saw—a buzzard in all its majesty sailing over the heart of one of the most completely industrialised areas of England. One might almost be tempted to recommend the convenient vantage of a dentist's chair to the eager bird-watcher, but to enjoy it to perfection one needs a dentist whose interest in ornithology is above mere professional enthusiasm.

* * *

The adage that it is an ill wind that blows nobody any good applies even to war, and though in the last three years I have often been irritated, occasionally depressed, and at times more than a little frightened, I have seldom been bored, and always profoundly grateful for the circumstances (even martial) that delivered me from those hypochondriacs that infest all practices. Whatever the Prime Minister may have to offer me in the way of blood and tears, I am freed, I hope for ever, from the woman whose sole (but incurable) complaint was a cold bottom. With this fundamental grouse she worked her way in strict rotation through the three partners that constituted my prewar practice, and though we all longed to warm it for her in an effective if unconventional way the necessity of paying our rent and feeding ourselves prevented us from telling her to go where her posterior would have been permanently cosy. The same applied to the anorexia nervosa who, though tempted with possets of cream by an anxious mother, continued to look like next year's rations. "It dates from the day she smashed up Uncle Fred's new car, Doctor. Very highly strung she is ... takes after me ... and of course it came as a great shock to her." It must have come as a great shock to Uncle Fred, but Sparrow Wrists patented hers first, and all that remains to Uncle Fred is a battered chassis and the faint suggestion that it was all his fault. No less maddening was a middle-aged woman who revelled in the unsuitable name of Wise, and till the outbreak of war suffered from mysterious and (as far as I was concerned) undiagnosed stomach symptoms. These took the well-known form of all her internals rising and fluttering like a lark in her scrawny throat. "Shelley's disease," muttered the senior partner when I relayed her history. "Hail to thee, blithe spirit! Bird thou never wert." He was more correct than he imagined for I was called to her one night to find she had stumbled dead drunk into the air-raid shelter, and was suffering from concussion. We weathered this distemper together, but afterwards she was a little shy of me and eventually took herself off to the new doctor (ever so clever!) round the corner.

These were, of course, the brighter stars in a long list of neurotics that haunted the surgery. One struggled with them, first medically, then psychologically, till exhausted by their capacity not to be cured one wrestled instead with the human desire to tell them to go out of one's life for ever, and the knowledge that as they had no intention of ever allowing anyone to cure them it was silly to put even their capitation fees into someone else's pocket. This view, sordid as it may be, did at least argue mutual freedom on the part of the patient and doctor. One endured them till that happy and never far distant day when one's temper wore a little thin and they betook themselves in a huff to other waiting-rooms. Once rid of them they provided rich food for laughter and became almost popular in contradistinction to that dreadful army of masochists who not only refused to get better—but wallowed in the harsh word, the black look, and the hollow moan that accompanied their visit. Even today I shudder when I think of them, and as one who means never to return to general practice I offer the following scheme as an infallible deterrent to the unwanted patient. It is specially designed for war-time, but no doubt a peace-time version could be evolved.

I have christened it temporarily "Supreme Patrifice," but put baldly it amounts to euthanasia for the useless. The method I suggest is as follows. When the medical sufferer's patience has finally run out of his boot heels, the surgery scourge should be invited to recapitulate the numerous symptoms that make life a burden for him, and in case his memory fails he can be jollied along with helpful references to his or her notes (if you've kept any), something in this style. "Now let me see, Mrs Mone, apart from this excruciating pain that circles your head, stabbing your eyes as it passes, and which naturally makes you wonder if you have a brain abscess, you are also a martyr to agonising spasms starting in your legs and rising to your stomach, so that it is impossible to eat anything. Yes, yes, I understand *perfectly*. This curious sensation always coincides with the icy hand that grasps your heart so that you feel you are *going* to suffocate. No of course I am not surprised that you begin to think of Aunt Amelia who died of angina. What? Oh, I'm sorry these heart symptoms are the aftermath of this dreadful giddiness that attacks you just before one of your *awful nerve storms*. Yes, yes. Insomnia. Oh, quite." You now prepare to launch the key phrase. Somehow you stop this flow of ailments and leaning forward murmur, "Under *such* circumstances life must be a burden, now don't deny it (they won't), a real burden, and therefore you are one of the people that I can safely recommend—with your permission—to the *Ministry of Health*. Now I want you to understand this is absolutely confidential." You thereupon hitch up your chair cosily near theirs, and rapidly outline a scheme by which they can save the country food, clothing, &c., by allowing you to eliminate them painlessly. All they have to do is to fill up a form for ministerial filing purposes, and in perfect privacy and at the Government's expense they can plunge fearlessly into that bourne from which no traveller returns. Stress is laid during this patter on the immense service they will be rendering their country by ridding it of such a dead-head, their happy release from a painful existence, and the complete secrecy that will prohibit anyone but yourself from knowing of their sacrifice. If they ever allow you to get as far as this, you give them several days to think it over and make final arrangements for their departure. I predict that in most cases they will sweep out in angry fright, and you will never set eyes on them again. If, however, by some horrible chance your patient should agree, you can always say the Government has changed its mind—it often does.

* * *

A fascinating disease this nephritis; I wish I knew something about it, but the more I read the more fogged I become. At present I have three cases on my visiting list. The first is that of a young man now 22, whom I have been "watching" since he was 7. All these years he has undoubtedly had chronic nephritis and appears to be no worse now than he ever was. Incidentally, for the past 5 years he has continuously run a slight temperature, the cause of which has confounded the local pundits. The second case is that of a man aged 60 with hypertension and a high blood-urea who has had what are presumably uræmic fits at intervals for the past 3 years at least, and seems no nearer his end than when first diagnosed. The third case is that of an arteriosclerotic, slightly osteo-arthritic, but otherwise tough septuagenarian lady who suddenly "blew up" with generalised œdema just before last Christmas Her arterial tension rose and she leaked great quantities of albumin but her blood-urea remained almost normal She had several bouts of "uræmic" vomiting during which she appeared moribund The œdema fluctuated but tended to increase, and in the faint hope of reducing it I gave her a couple of quite small doses of 'Salyrgan' and a pot cit mixture Nothing dramatic happened, but four or five days later she suddenly got rid of all her œdema and indeed of all her symptoms She is now eating ravenously and gaining weight The urine now contains only a trace of albumin and the blood-pressure has fallen to its usual level She has, in fact, behaved exactly like a case of "pregnancy kidney," which recovers completely after the birth of the infant, but in this case pregnancy can, I think, be excluded

* * *

Coming back from a well-timed midder early this morning I joined the birds in their songs of praise Let us now praise District Nurses and the Committees that begat them, for they are daughters to the aged, mothers to the motherless, sisters to them in labour, whose hands, holy but sterile, heal the sores of the outcast and the brains that have broken, clip the beards of the ancients and the nails of them who cannot bend or see, who perform the task of the menial and are paid with the thanks of the lowly and the privilege of service, who come like sun to the prisoned and song to the cottage, who bring the news of the village and the jest of the market, and bear a message from one who is sick to another, who ease the way of the dying and the crown of the baby, who watch the going of life with stertorous gliding and its coming with bulge and recession, oft keeping vigil by candle, who must walk in men's ways alone, warily treading between the footmarks of gossip, the ruts of malice and the paths of the partisan, who oft see the dawn of a day, but know not the labours it's bringing O apostles of soap and sanity, O black-bagged friars of country lanes, Angels on Push-bikes, I salute you, District Nurses!

* * *

It seems to me high time that the taking of notes at lectures was prohibited and the student supplied before each lecture with a cyclostyled or typed note, as full as possible, of the points to be discussed during the lecture You may say that this would reduce the lecture to the level of a tutorial or grind class But why not? Why should not every lecture given to students be 100% efficient in teaching value? My own recollection of student days, now many years ago, is that more than half the time spent at formal lectures was wasted Even the BBC for their lessons to schools publish booklets on each subject which are often referred to by the speakers Formal lectures were all very well in the old days of the Continental schools of medicine, because the common language was Latin Lectures then were probably given at dictation speed, for a lecturer had not only to make his subject clear to students of different nationalities but had also to avoid the charge of "false" Latin which might be levelled against him if he spoke too quickly and slurred his words Those modern lecturers who insist on pencil and notebook should either speak at dictation speed or make medical students pass a test in shorthand at their matriculation This might at least result in an improvement in the handwriting of the profession, a worthy object in itself

* * *

On my way home from an outlying village I gave a lift to a 12-year-old cockney evacuee boy returning to his billet from school He was a boy of few words so that our conversation partook somewhat of the nature of a cross-examination "How long have you been down here?" I asked "Two years" "Like it?" "Yes" "Want to stay here for good?" "No" "Where's your home?" "Tooting" "You want to go back to Tooting?" "Yes" "Any brothers or sisters?" "One brother" "Where's he?" "Home" "What's he doing?" "Printing trade" "What's your father's job?" "Printing trade" "And your grandfather?" "Printing trade" "What do you want to do?" "Printing trade" It looks to me as though this family has a single-track mind

Obituary

ERNEST LLOYD JONES

M D CAMB

Dr Lloyd Jones, senior consulting physician to Addenbrooke's Hospital, Cambridge, died on Sept 16 in his eightieth year Born at Bowdon, Cheshire, he was educated at Manchester Grammar School and went to Downing College, Cambridge, with a Clothworkers' scholarship in 1882 In 1888 he qualified from Bart's where he won the senior science scholarship and he proceeded to the MD degree in 1891 Three years later he was awarded a BMA research scholarship for his work on the causes of chlorosis This subject remained one of his abiding interests and many of his writings deal with the blood in health and disease He also published in 1899 a study of the topographical distribution of cancer Lloyd Jones returned to Cambridge to work as demonstrator of pathology under C S Roy and soon joined the staff of Addenbrooke's as pathologist In all he was associated with the hospital for over forty years, and when he retired from the honorary staff in 1927 he continued his private practice till about eighteen months ago H B R writes — "Lloyd Jones had a real concern for his patients and gave his professional services without thought of remuneration and often, especially during the last few years of failing strength, without consideration for his own health He was kindly and gentle, and his patients, both in private and hospital practice, looked upon him as a real friend who knew how to brace and comfort them with his cheery stories" Lloyd Jones gave freely of his time to Papworth Village Settlement, where he was for a long time a member of the visiting staff and latterly chairman of the committee of management As a young man he had explored the Hoyle's Mouth and Coygan caves in South Wales and some of his fossil specimens are to be found in Cambridge museums On his rambles on seashore and countryside the cries and habits of birds absorbed him, and it was delightful to watch him care for special plants or animals which he had befriended He was a fellow of the Geological Society and of the Cambridge Philosophical Society, and at the time of his death was writing a book on foraminifera

In 1901 he married Constance Mary Brooke and they had one daughter

ARTHUR BROWNLOW MITCHELL

O B E, M B R U I, F R C S I

WITH the death on Sept 3 of Lieut-Colonel A B Mitchell, the older generation of Ulster surgeons lost one of its greatest men For fifty-two years he had served the voluntary hospitals of Belfast, for after he retired from active practice he continued his share in their direction until a few days before his death at the age of 77

In 1893, three years after his graduation, he became assistant surgeon to the Ulster Hospital for Children and Women, and in the following year, when still only twenty-nine, he was elected an assistant surgeon to the Royal Hospital, later the Royal Victoria Hospital He was senior surgeon when in 1928, two years before reaching the age for retirement, a finger-prick during an operation set up an infection which endangered his life for many weeks, left him with a crippled hand, and ended his operating career But his energy and enthusiasm were unabated, and in 1930 he was elected chairman of the board of management of the Royal Victoria Hospital, an office he held till his death during perhaps the most progressive period in the history of the hospital He saw its amalgamation with the Royal Maternity Hospital and the erection in quick succession of a new pathological department and new nurses' home, the Musgrave clinic for private patients, extensions to the wards, and finally a new isolation block, so that the one boundary wall now encloses a hospital colony of 706 beds During the last war Colonel Mitchell organised a military orthopædic hospital working with the Ulster Volunteer Force Hospital, and from 1917–19 he was a member of the Army Medical Consultant Council Till a few months before his death he was a member of the senate of the Queen's University, and in 1935 he was elected one of the

University members to the Northern Ireland House of Commons

Mitchell was in the fullest sense of the word a general surgeon—his published work included papers on acquired flat foot excision of the entire scapula and repair of injuries to the skull by perforated plates—but his greatest interest was in abdominal surgery, and especially in the surgery of the stomach and duodenum He was one of the pioneers of the operative treatment for perforated peptic ulcer and in 1903 he published in THE LANCET a paper on the surgery of gastric ulcer, while as early as 1909 he was able to report 23 operations for perforated duodenal ulcers with only one death Within the abdomen he combined speed of decision and execution with a gentleness and delicacy like that of Moynihan who knew and admired him His enthusiasm covered every detail of pre- and *post-operative treatment* He was always in hospital a few minutes before he was expected wasted no time but never forgot, nor allowed any of his staff to forget the essential humanity of medicine He knew his hospital patients as well and esteemed them as highly as his private ones, and took an interest not only in them but also—how much rarer—in their relatives

As a teacher, Mitchell was outstanding An excellent speaker he was dogmatic enough to impress the basic principles on undergraduates He was at his best at the bedside where he took delight in demonstrating physical signs and for him the most commonplace conditions yielded fresh material In every way he fitly filled that calling which “ should exact the utmost that man can give—full knowledge exquisite judgment and skill in the highest to be put forth not at any self-chosen moment, but daily at the need of others

EDWIN LANCELOT HOPKINS

MC MRCS DPH DPM

Dr E L Hopkins who died on Sept 10 at the age of 53, had been medical superintendent of the Derbyshire County Mental Hospital for over ten years His charm sense of humour and kindly sympathy endeared him to his patients and he had served them well for he had done much during his stay at Mickleover to improve their living conditions, methods of treatment and to give them a fuller sense of security and freedom of outlook He avoided hasty decisions, but his judgment was sound and the psychiatric clinics which he began at Derby and Chesterfield were the beginning of plans which the war unfortunately postponed As a student Hopkins was an all-round athlete and played rugby for the London Hospital and for Somerset After qualifying in 1916 Hopkins at once joined the RAMC and was awarded the MC in Mesopotamia for conspicuous gallantry and devotion to duty while attending the wounded under fire. When he was demobilised he held an appointment in the Ministry of Pensions and took his DPH in 1921 He joined the LCC mental hospital service shortly afterwards and held posts at Bexley, Hanwell and Ewell before he was appointed to West Park hospital He married Miss Violet Joyce of Milverton in 1916 and he leaves her with one daughter

Dr JOSEF LOEBEL of Franzensbad whose death is announced from Czecho-slovakia, was the author of a semi-popular history of medicine and the medical sciences which attracted some attention when it was published here in translation in 1934

WOMEN DISPENSERS —The Ministry of Labour and National Service has appointed the Central Pharmaceutical War Committee to place in new posts women pharmacists, dispensers and drug hands who come within the Employment of Women (Control of Engagement) Orders Women subject to the orders who seek new employment should apply to the committee at 17, Bloomsbury Square London, WC1, and employers should send the committee particulars of any vacancy they wish to fill The National Association of Women Pharmacists, 18, Sheepcote Road, Harrow, Middx, may also receive notifications from employers and employees, but the responsibility for placing the women rests with the central committee. Arrangements for Scotland are under discussion between the Scottish Central Pharmaceutical War Committee and the Ministry of Labour and National Service, and for the present employers should continue to apply to the local office of the Ministry of Labour

Letters to the Editor

ANÆMIA IN PREGNANCY

SIR —May I protest against the loose use of the term “ pernicious anæmia ” to cover cases of the sort described by Miller and Studdert in THE LANCET of Sept 19 (p 332) The withdrawal of pernicious anæmia from the undifferentiated pool of the anæmias is one of the major triumphs of medicine within the last twenty years Pernicious anæmia is now a firmly established and clear-cut entity ; of these there are few enough in medicine and it seems a pity to ignore those that we have Ætiologically we know that pernicious anæmia depends upon failure in the production (or pace *αχρησια* the utilisation) of Castle's intrinsic factor of the antianæmic principle of liver That we remain in ignorance of the nature both of the intrinsic factor and of the antianæmic principle is regrettable but offers *no grounds for ignoring their* existence Further it is accepted that the diagnosis of pernicious anæmia demands a combination of gastric achlorhydria and of a megaloblastic anæmia Of the 23 cases reported by Miller and Studdert 20 showed free HCl in the gastric juice and under the terms of the definition at once fall outside the category of pernicious anæmia Whether the 3 remaining cases showed a megaloblastic picture either in blood or marrow in combination with the achlorhydria is not, I think, made clear Whether pregnancy may occur in the face of pernicious anæmia seems unknown and if we go on calling any form of anæmia occurring in pregnancy ‘ pernicious ’ it is likely to remain so

As pointed out in your leading article in the same issue the grave anæmias of pregnancy are mainly nutritional and Miller and Studdert draw attention to the nutritional element in their own cases It is to be remembered that Minot and his collaborators started the work which went so far to the elucidation of the problem of pernicious anæmia on the assumption that it also was nutritional it took some years to reach the realisation that this was not the case It would be a pity should this established fact become obscured

The point is of more than academic interest since once the diagnosis of pernicious anæmia has been established the patient must be instructed to continue with liver treatment throughout life , this does not apply to the class of case reported by Miller and Studdert It is for these reasons and with no intention of decrying the value of their careful observations that I am moved to make this plea for the rigorous restriction of the term “ pernicious ” as applied to anæmia

Wolverhampton.   S C DYKE

BRONCHIECTASIS

SIR —I read with interest in your issue of Sept 19 the report by Newton and Berridge of bronchiectasis in serving soldiers as a number of similar cases from another service have recently passed through my hands I notice that in their series all cases (four in number) involving the upper lobe were of the saccular type This has also been my experience and I would welcome the opinion of others on the matter The question is of significance in connexion with ætiology If the saccular type has a congenital basis and the fusiform and cylindrical types an infective one this distribution can be readily understood

My own interest has been aroused by two men whom I have investigated in hospital in the past few weeks One showed a saccular bronchiectasis limited to an upper lobe the lower lobe being normal The other—not a case of bronchiectasis, but found on routine radiography —showed a rarefaction of the left upper lobe with faint cystic markings on the straight film ; no lipiodol could be introduced into this lobe and bronchoscopy revealed that the area did not communicate with main bronchial tree It is tempting to suggest that in both these cases the ætiology was the same—a congenital cystic condition of part of the lung which in one case communicates and has become infected and in the other does not communicate and has remained harmless If this is so it supports the view that the saccular type of bronchiectasis represents infection of pre-existing congenital dilatations of the bronchi

C P PETCH

BRONCHIECTASIS

SIR,—Drs Martin and Berridge are correct in drawing attention to the fact that bronchiectasis may cause relatively mild symptoms but it would be wrong if the impression were engendered that bronchiectasis is ordinarily a disease that can be taken lightly Their observations must be viewed in proper perspective, and that is not the perspective of bronchiectasis itself but of disease as a whole Much the same paper could have been written about at least a dozen other diseases such as appendicitis peptic ulcer, gall-stones, varicose veins or even pulmonary tuberculosis—suppose their paper was headed " Pulmonary tuberculosis without disability Report on 25 cases diagnosed by early symptoms and confirmed radiologically ' (or even discovered by routine radiography) Pulmonary tuberculosis may be present without disability and may never cause more than transient disability We know that most diseases have minor variants or minor phases , bronchiectasis is no exception Martin and Berridge's cases are all highly selected, being taken from men passed into the Army as *apparently* fit , this first premise largely vitiates any wide application of their observations to bronchiectasis in general Again, it is strange to refer to the condition as one without disability when all the 25 cases had gravitated to hospital and all were recommended for discharge from the Army as permanently unfit In passing, this would seem far too sweeping a condemnation of really mild cases of bronchiectasis It is, moreover, incorrect to say that a man cannot be made fit for military service by lobectomy since I and my thoracic surgical colleagues have had patients so treated who have been accepted for or retained in the Services and are absolutely fit

Harley Street, W 1 R C BROCK

POST-ARSPHENAMINE JAUNDICE

SIR,—Your annotation of Sept 5 is opportune There can be little doubt that the "impression that syphilitic treatment is too often being complicated by jaundice" is widespread, and it is to be hoped, as suggested, that the Services may publish their figures You give the reported incidence of jaundice in cases treated with arsenicals as from 0 6% to 5% In a detailed paper by Sager (1936), however, the following figures of postarsenical jaundice are quoted Filhiol (1930), 7 7% , Milian Lotte and Delarue (1928), about 20% , Ruge (1931), about 19% in the German Marine Corps , and Gutman (1922), 7 4% Although, when the original articles are carefully perused, the evidence for these figures is not conclusive, it suggests that the incidence may be higher than 5% if looked for Dr Curtis in his letter mentions an incidence of between 25% and 30% among cases treated in the years 1937–40 at the Whitechapel Clinic

In my own experience, although low figures for post-arsphenamine jaundice have been found in small series of cases, when long series are studied the figures are considerably higher than those given in your annotation I hope shortly to publish in some detail the results obtained during the thirteen-year period, 1929–41, at the department for venereal diseases here Contrary to the statement in your annotation that there has been no evidence to correlate jaundice with any one arsphenamine preparation my analysis shows greatly different incidence after the various arsenicals, especially if arsenoxide ('Mapharside ') is included Mapharside gave the lowest jaundice rate, and also the shortest average illness, and its substitution for the arsphenamines has considerably reduced mortality as well as morbidity, while the clinical and serological results have never been so satisfactory

Your annotation mentions the possibility of the jaundice being due to a virus One might envisage two possibilities inoculation during treatment through faulty technique, or activation by the drug of a virus already present in the body The first is improbable, as during 1934–35 when NAB was used as routine the incidence of jaundice reached such alarming proportions that syringes were boiled before each injection without diminishing the incidence of jaundice The second possibility is interesting In the same years 1934–35 there was no abnormal rise in the incidence of jaundice amongst the patients in the other departments at St Thomas's, as would be expected if a jaundice-producing virus was at work The evidence is unconvincing in spite of the work done by the German (1932) and Scandinavian (1939) observers cited in your annotation Ruge epidemiological work, quoted to support the view that post-arsphenamine jaundice was due to " infectious hepatitis unrelated to syphilis or the arsenicals " can also be used to support the hypothesis that the drug and no a virus, is the cause, as he gives figures showing that the incidence of post-arsphenamine jaundice is less by one third in cases treated with sodium arsphenamine than in those who were given neoarsphenamine Moreover, why choose a complicated hypothesis of an unknown virus being activated by a chemical substance which itself is known to be a liver poison, when the simple hypothesis that the liver poison causes the liver damage fits the facts ? Further, as you observe, the incidence of this jaundice has gone up with the introduction of the arsenobenzene preparations, as also has dermatitis

My experience leads me to believe that the percentage and severity of post-arsphenamine jaundice is reduced appreciably by substituting arsenoxide for the arsphenamines and that the spirochæticidal value of arsenoxide is greater than that of the neoarsphenamines Sir Sheldon Dudley informs me that these conclusions have been confirmed by the results so far obtained in the Royal Navy

St Thomas's Hospital, S E 1 T ANWYL-DAVIES

PRIVATE PRACTICE

SIR,—In the controversy that has long been waged on the merits or demerits of private practice or some other method or methods of practising surgery and medicine is not a rather important point usually overlooked ? We are still living under a political system called " democracy," which in theory at any rate is supposed to prefer private enterprise, private initiative, and the rights and responsibilities of individuals to their nationalisation or regimentation or socialisation under a Communist, or Socialist, or Fascist regime Indeed, many of us are under the impression that the great sacrifices which this war entails are made in the cause of Christian democracy, at least that is what our chief men in statecraft and diplomacy are always telling us Surely then nothing but some extreme calamity, affecting the whole nation and rendering impossible any kind of private enterprise in any sphere of human activity, could justify the nationalisation of the most personal and the most individualistic vocation in the world—namely, that of medicine X.

MD CANTUAR

SIR,—Your note (Aug 29, p 267) on the grant of a degree in medicine by the Archbishop of Canterbury appears to have a bearing upon the following incident related in the House Book of the City of York under the date July 3, 1598

> " William Padmore, surgeon, was complained on by ye company [of Barber Surgeons] for exercising chirurgery in this cittie , not being a freeman, who said for excuse yt he was allowed and licensed to practice by my Lord's Grace under his seal , but ye court did not think him to be excused thereby but ordered him to pay penalty in ye surgeon's ordinance, which is two shillings per diem soe long as he practised, unless he can quit himself by law and upon the 28th July 1598 he refused either to pay ye said penalty or to take his freedome , whereupon he was comitted till he paid ye said penalty, and on 20th October 1598, it was agreed yt William Padmore shall be made free for £6 13 4 "

The Barber-Surgeons' ordinances prohibited practice or admission to their company until the applicant had obtained his freedom Everyone who proposed to practise surgery in York was compelled to join the company or be expelled from the city Moreover within one month of being made a freeman he was under the obligation to read a lecture on anatomy or surgery Conversely any freeman or woman who consulted a non-licensed surgeon was laid under the heavy penalty of a forty-shilling fine

It seems most probable that the licence claimed by Padmore refers to that under the seal of the Archbishop of Canterbury, for it does not appear that a similar power was vested in his Brother of York In this controversy the obstinacy of both parties resulted in a compromise But there was clearly more in the quarrel than meets the eye, for Padmore's name appears in the previo r in the Roll of Freemen where he is described as " Surgion " He was probably not a native, whereby he might have become free per patrem A number of physicians, some of whom were foreigners, did become freemen and practised medicine

The Robert Thoroton you mention as receiving the MD Lambeth 1663 was born in 1623 at Car-Colston, Notts, and settled down in practise there but " finding that he could not 'keep people alive for any time' decided 'to practise on the dead' and devoted himself to antiquarian pursuits He had his stone coffin prepared some years before his death 'ut post mortem corpus ejus intemeratum quiesceret' " [D N B lvi, 313]

Birmingham G A AUDEN

UNSIGNED REVIEWS

SIR —Perhaps it is because I regard Prof R A Fisher's published knowledge almost with veneration that I hasten at once to his support I read *Nature* regularly first, before even my *Lancet* and the other lesser medical journals I feel that I am in a position to judge that the reviews in *Nature* are not only better but much more reliable than anything in the medical world I cannot find time to search through years of back numbers for instances, but the event has occurred so often that I have come to regard it as an axiom that *Nature*, apart from being the best of all scientific media, is the best guide to reviewed scientific books of all kinds, just as *Punch* is the best guide to general literature and fiction

It had not occurred to me that the signed review was necessarily the more careful Certainly it is more satisfying to know who is writing , and, now that Professor Fisher has pointed it out, there is strong presumptive evidence that signed reviews will be the more meticulous Even Mr Punch's staff of " learned clerks " have recently taken to adding their initials Perhaps, therefore, you would reconsider the matter, and quietly " liquidate " your annotation which carries no conviction whatever

Chiswick W 4 THOMAS NELSON

TRAINING FOR CHILDBIRTH

SIR,—Some of us had hoped great things from the joint report issued by the Medical Women's Federation and the Ling Physical Education Association on the results of gymnastic training in relation to childbearing The conclusions reached seem to show that it is no worse for the mother than no training at all and that it is not harmful As you point out, it must be beneficial to the prospective mother to have increased suppleness of all joints and well-developed abdominal and pelvic muscles A more important inquiry is can childbirth be made easier by antenatal exercises ? Undoubtedly it can We have recently been taught that in preparation for childbirth the pelvic joints in woman become 2½ times more flexible than in the unimpregnated state Antenatal exercises are merely making use of this natural fact and are designed to promote general flexibility of the whole body while paying special attention to lumbar spine, sacrum, pelvic joints and ligaments My experience has been that they not only improve the expectant mother's health and sense of well-being, but fill her with hope and give her a sense of security and confidence in her ability to bring matters to a successful conclusion She feels she is now an active member of a team all in training for an event to which each one looks forward, the birth of her own child, and so she shows intelligent interest and pride , during confinement she hopes she is keeping up the reputation the class has already earned Records of the confinement of women who have had such training during their pregnancy show excellent results No trace of fear or anxiety and complete cooperation during labour are outstanding features

Hampstead Way, N W 11 KATHLEEN VAUGHAN

SURFACE FREEZING FOR DEEP PAIN

SIR,—Referring to the uses of ethyl chloride spraying described in your issue of Sept 5, I have used ethyl chloride extensively since 1924 both in dermatology and surgery and have arrived at the following conclusions

1 Acute inflammation of joints, extensive tears of ligaments and fractures are a contra indication

2 A case that does not respond favourably after two or three applications should be considered unsuitable for treatment

3 Red haired diabetic and hyperthyroid subjects are especially liable to skin injury

4 Ethyl chloride may cause skin injury resulting in lupus, as Prof R O Stein of Vienna and others have shown

5 It is advisable to use, after the ethyl chloride spraying, a liniment consisting of acetone, ether, camphor and alcohol This I have found helpful in prolonging the anæsthetic effect and shortening the duration of disability

6 Parts treated should be covered with " Vaseline " or zinc paste It is better not to apply any supporting bandage

The effect of ethyl chloride spraying is dramatic in the more chronic cases of stiffness of joints, contraction of tendons, &c , chronic shoulder pain, subdeltoid bursitis, old knee injuries with incarceration of cartilage, contracted peroneal tendons and such like In many cases which had attended as outpatients for as long as eighteen months it was possible to effect a cure by one or two applications of ethyl chloride and simple movements Ethyl chloride has been used successfully in alleviating pain in biliary colic (tenth intercostal space, ninth dorsal segment) and angina pectoris (third intercostal space, left sternal border) I have relieved a persistent hiccough by freezing the skin over the phrenic nerve (sterno-clavicular articulation)

London, W 1 J E O'LOGHLEN

Infectious Disease in England and Wales

WEEK ENDED SEPT 19

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 1882 , whooping-cough, 1150 , diphtheria, 878 , paratyphoid 8 , typhoid, 13 , measles (excluding rubella), 2998 pneumonia (primary or influenzal), 401 , puerperal pyrexia, 136 , cerebrospinal fever, 72 , poliomyelitis, 29 , polio-encephalitis, 1 , encephalitis lethargica, 1 , dysentery, 184 , ophthalmia neonatorum, 93 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Sept 16 was 1423, including scarlet fever, 390 , diphtheria 115 , measles, 171 , whooping cough, 215 enteritis 79 , chicken pox 65 , erysipelas 32 , mumps 32 poliomyelitis 1 dysentery 19 cerebrospinal fever, 8 puerperal sepsis 28 , enteric fevers 8 german measles, 2 , other diseases (non infectious), 147 not yet diagnosed 81

Deaths,—In 126 great towns there were no deaths from scarlet fever or the enteric fevers, 4 (0) from measles, 9 (0) from whooping-cough, 16 (1) from diphtheria, 69 (10) from diarrhœa and enteritis under two years, and 10 (2) from influenza The figures in parentheses are those for London itself

A fatal case of an enteric fever was reported from Greater London There were 7 deaths from diarrhœa at Birmingham, and 5 each at Hull and Liverpool

The number of stillbirths notified during the week was 206 (corresponding to a rate of 34 per thousand total births), including 21 in London

---

FORTIFIED FOODS —Margarine now contains 500–600 international units of vitamin A and 60 IU of vitamin D per ounce The addition of prepared chalk to National wheatmeal flour has now begun Major Lloyd George announced in Parliament in April (see *Lancet*, April 25, p 517) that 7 oz of calcium carbonate is to be added to each 280 lb sack of flour, and the addition is now proceeding district by district

ROYAL NATIONAL THROAT, NOSE AND EAR HOSPITAL —The following lectures are to be given at this hospital, Gray's Inn Road, London, WC1, on Fridays at 4 PM during the coming months Oct 2, Mr G H Howells, ethmoiditis , Oct 16, Mr Lionel Colledge, the complications of middle ear suppuration , Oct 30, Mr F W Watkyn-Thomas, the treatment of deafness , Nov 13, Mr A R Dingley, symptoms and treatment of frontal sinusitis , Nov 27, Mr W G Scott Brown, war time injuries , Dec 11, Mr C Gill Carey, emergencies in nose, throat and ear surgery , Jan 8, Mr S A Beards, petrositis , Jan 22, Mr F C Ormerod, tuberculosis of the upper respiratory tracts , Feb 5 Mr N Asherson, acute emergencies in ear, nose and throat , Feb 19, Mr J C Hogg, cardiospasm , March 5, Mr S E Birdsall, sinusitis in children , and March 19, Mr J D McLaggan, chronic suppurative otitis media The lectures are open to all members of the medical profession without fee

Notes and News

FREE CHILDREN

The latest addition to "Contributions to Modern Education"[1] describes an unusual investigation which must have proved stimulating to those taking part Two series of schools are contrasted orthodox (B) and experimental (A) Miss Gardner has a bias in favour of adventure in education, and the results of her survey give her a perfect right to it—such an overwhelming case in fact that it is a pity she shows an enthusiasm for one type of school at the expense of the other Her use statistically of average deviation rather than the usual mean deviation might be criticised, but her conclusions speak for themselves In the A as compared with the B schools there was less formal teaching of the three R's, and more time was given to free play, handwork, and experiment Questions, talk and movement in class were encouraged The observations made covered school subjects, drawing, physical skill, concentration, neatness, self-confidence, artistic and linguistic expression, and sociability in the playground as well as in the class-room The children were carefully matched in intelligence, social setting and age in the two kinds of school On achievement, the children educated in the free type of school undoubtedly do better, and do it earlier, than the others There is one exception—neatness in writing—which at seven is a poor sort of consideration anyway The importance of this study lies as much in the liberation of the infant school teacher from a dreary routine of lessons as in the emancipation of the child from an equally boring series of sessions which have to be endured It would be interesting to repeat the experiment in Scotland, where play in schools as a substitute for lessons is still highly suspect

Prisoners of War

The following RAMC officers have been posted as prisoners of war

Major J A G Carmichael, MRCS, WS/Captain H D Fleming, MRCS, Captain James Gendle, MB LPOOL, WS/Captain C D Holdstock, MB LOND WS/Captain Geoffrey Lancaster MB MANC, WS/Captain H J McPherson, MB EDIN, WS/Captain J C Mustardé, MB GLASG WS/Captain A P Norman, MB CAMB, WS/Captain N C Rogers MB LOND, WS/Captain J A Sutherland, MB GLASG, and Captain Per Turner, MB SHEFF

Medical Honours

The following awards have been made to medical men in the Services

DSC—T/Surgeon Lieutenant H S A Corfield, LMSSA RNVR, T/Surgeon Lieutenant K C Jeffery, MB LOND, RNVR, T/Surgeon Lieutenant R D Robinson, MRCS, RNVR

MC—Captain A A Byrne, LRCPI, RAMC, Captain C R Tilly MRCS, RAMC, Captain Eric Townsend, MD EDIN, RAMC, Captain James Watt, MB GLASG, RAMC

The MBE has also been awarded to Dr R H Moyes, deputy MOH for Kingston on Hull

Throughout enemy air raids Dr Moyes has played an important part in succouring wounded and victims and in encouraging the personnel of civil defence services In one raid he assisted many trapped people and gave morphia to ease the sufferings of those who could not be immediately released This necessitated crawling into tunnels when debris was still falling, Dr Moyes has been medical officer at many incidents and he has always maintained a high standard of professional skill and courage

British Medical Association

Dr Peter Macdonald (York) has been elected chairman of the representative body and Dr J B Miller (Glasgow) deputy chairman

Royal Sanitary Institute

A meeting of the institute will be held at 11 AM, on Saturday, Oct 10, at West Bromwich, when Dr W S Walton will speak on some practical health problems of today from the MOH's standpoint Mr W W Foakes will deal with the same subject from the point of view of the sanitary inspector On Wednesday, Oct 21, at 2 30 PM, a meeting will be held at the Institute, 90, Buckingham Palace Road, London, SW1, when Dr Henry MacCormac, Dr Thomas Standring and Major C. G Johnson will open a discussion on scabies

Royal College of Surgeons of England

Arnott and Erasmus Wilson demonstrations will be given at the college in Lincoln's Inn Fields, London, WC2 on Monday Tuesdays, Wednesdays, Thursdays and Fridays at 4 PM during October

The first will be given on Oct 12, by Dr A J E Cave who will speak on the olfactory parts of the brain Other lecturers are to be Mr L E C Norbury, some forms of intestinal obstruction, Dr Cave, the visual parts of the brain, Mr C E Shattock, diseases of the testis, Dr Cave, the mid brain and basal ganglia and epidermal structures, Mr R. Davies Colley, bone tumours, Dr Cave, mesenteries, fold and peritoneal ligaments, Mr Shattock, diseases of the breast, Dr Cave, unspecialised mesodermal derivatives and neuro osseous relations, Surgeon Rear-Admiral C P G Wakeley injuries of the skull and brain, Dr Cave, articulations of the axial skeleton and anatomy of the shoulder girdle

All the demonstrations will be open to medical practitioners and advanced students

University of Wales

Dr Nancy Rogers and Dr Julius Naftalin have been appointed assistant lecturers in the department of pathology and bacteriology

The Index and title-page to The Lancet, Vol I, 1942, which was completed with the issue of June 27, will be ready next week A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Appointments

Allen W H E, MRCS RSO at Royal S Hants and Southampton Hospital
Bliss Theodore, MRCS RSO at Corbett Hospital, Stourbridge
Culley, A R, MD WALES, DPH MOH and School MO for Glamorgan
Dally, J F Halls MD CAMB, MRCP medical superintendent of All Saints Emergency Hospital, Bromsgrove
Fletcher Anne, MRCS temp asst MO at city maternity home, Handsworth Birmingham
Jeans, Alberta MRCS surgical registrar at the Royal Victoria Infirmary, Newcastle-on Tyne
MacFarlane, J W MD GLASG FRFPS Workmen's Compensation, medical referee for Glasgow, Lanark, Hamilton and Airdrie
Sambrook D K, MB LOND, RSO at Leigh Infirmary
Sommerville, J A, MB GLASG examining factory surgeon for Saddel and Skipness, Argyllshire

Births, Marriages and Deaths

BIRTHS

Denny Brown—On Aug 23, at Boston, U S A, the wife of Prof Derek Denny-Brown, FRCP—a son
Elliot Smith—On Sept 21, in Oxford, the wife of Mr Arthur Elliot Smith, FRCS—a son
Golden—On Sept 17, at Norwich the wife of Lieutenant M B H Golden, RAMC—a son
Lister—On Sept 20 at Twyford Bury, Bishop's Stortford, the wife of Major Arthur Lister, FRCS RAMC—a son
Morse—On Sept 19, at Midhurst, the wife of Dr Philip Morse—a son
Parke.—On Sept 18, at Liverpool, the wife of Mr William Parke FRCS—a daughter
Robinson—On Sept 20, at Rochester, the wife of Surgeon Lieutenant Alan Robinson, RN—a son
Ward—On Sept 19, in London, the wife of Dr P M Ward—a son

MARRIAGES

Martin—*Hurst—On Sept 19, at Bowdon Cheshire, William Desmond Martin, Lieutenant* RAMC *to Evelyn Pamela Hurst*
Pearce—Wynne—On Sept 26, at St. Ives, Huntingdonshire Gerald Huxham Pearce FRCS, to Eileen Barbara Wynne
Semple—Dewar—On Sept 22 in Glasgow, Thomas Semple, Lieutenant RAMC, to Elspeth Roubaix Dewar

DEATHS

Bell—On Sept 19 at Radmoor Thomas Bell MD GLASG, JP
Dring—On Sept 21, at Tenterden Kent, William Ernest Dring MRCS JP aged 90
Fawcett—On Sept 22, in Bristol Edward Fawcett, MD EDIN, FRS emeritus professor of anatomy
Hinchco—On Sept 21, Harold Hinchco, MRCS, DPM, of Langham Court Wimbledon
Kellett Smith.—On Sept 23, Joseph Stanley Kellett Smith FRCS DMRE of Cheltenham
Kerr—On Sept 21, at Southport, James Rutherford Kerr, CBE CH M GLASG

EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS*

R. R. TRAIL, M.C., M.D. ABERD., F.R.C.P.
WING-COMMANDER, R.A.F.V.R., PHYSICIAN TO THE ROYAL CHEST HOSPITAL, AND SURGICAL UNIT, PAPWORTH

IN the past ten years more papers have been published on this subject than on any other aspect of chest disease. This implies something deeper than intrinsic interest. It reflects a feeling of uneasiness, even a sense of disappointment, however much this may be camouflaged by a repetition of our difficulties and by a hope that an ever-spreading knowledge of premonitory symptoms and early signs will put an end to our continuing failures. We discuss the early diagnosis of pulmonary tuberculosis, and are still a long way from the diagnosis of early pulmonary tuberculosis, except in a disappointingly small percentage of cases. We have no cause for complacency.

It is true that the last twenty years have seen progress in certain directions. Propaganda directed at the public and the general practitioner has been widened; we have set up better equipped public-health services, and have been urged to greater efforts in diagnosis by noting the encouraging immediate and end-results of modern collapse therapy. On this last point Dr. G. S. Todd of King Edward VII Sanatorium, Midhurst, has kindly supplied the following figures. Among sputum-positive cases, the five-year survival-rate after discharge from the sanatorium averaged 44% before the introduction of collapse therapy in 1925; after that date it rose to 60% until 1935, when it again rose to nearly 70%. Furthermore we have been heartened by the study of graphs of falling national death-rates. Thus, the tuberculosis death-roll for England and Wales in 1938 was 26,178, a fall of 10,456 since 1928—that is, an improvement of 31 per 100,000 of the population in 10 years.

Detailed analysis of the present position in respect of the number of sufferers and the extent of disease at diagnosis is, however, not so pleasant. In that same year of 1938 about 230,000 cases were under observation at the tuberculosis dispensaries of England, Scotland and Wales, while 65,000 new cases were notified, and there were 30,000 deaths from the disease. Moreover it claimed half the total deaths from all causes at ages between 15 and 24, an age-group particularly important in national economy, and the one in which the decline in mortality has continued at a slower rate than in any other. To this we must add that the increase in deaths from all forms of tuberculosis between 1939 and 1940 was 3005, and that returns for the respiratory form in 1941 are 13% above the average for 1938 and 1939. Indeed, if we draw conclusions from experience of the last war, we may expect now a temporary levelling of this comparative increase, and then a sharp rise in both incidence and mortality over the next two years.

What of the results of increased propaganda and improved facilities for dispensary diagnosis? Two comparative sets of figures will enlighten us. In 1927, of adult patients admitted to residential treatment for pulmonary tuberculosis under the London County Council scheme, only 6% were classified as B I at the time of admission; 78.4% were classified as B II or B III. In 1937, that is 10 years later, 5.7% were B I and 80.3% B II or B III. These facts speak for themselves. We *cannot* claim that any advance has been made by propaganda, and what is much more instructive is the fact that the best possible tuberculosis services with every modern equipment made no improvement towards earlier diagnosis in 10 years.

This depressing story has a still more depressing ending. By the extent of disease at diagnosis the majority of these unfortunates are unsuitable for modern methods of treatment and but few survive for 5 years after discharge from sanatorium treatment. They show a poor economic return and a minimal gain in social happiness for the care and expense afforded them. Thus, patients discharged in 1932 from LCC residential institutions and traced till 1937 give the following survival-rates—for B II cases, 41.2%; for B III cases, 7.9%. When we place against these figures the survival-rate of 81% in B I cases, the necessity for early diagnosis with all its attendant advantages to the individual in efficient treatment and to the national economy in the return of patients to work is self-evident. The after-history of Midhurst patients with stage of disease comparable to B I shows an improvement in the five-year survival-rate from 86% in 1930–32, to 93% in 1933–35.

Is there any cause in the present conditions governing diagnosis that by itself denies us the power to discover disease at an earlier stage? Why do we fail in spite of trained observers and continually improving health services? The answer is not far to seek. For diagnosis, doctor and patient must meet. Up to the present, in civil practice, a doctor must perforce wait until the patient comes to him. It is only with the arrival of symptoms, and not always then, that the patient will seek advice. To ask the general practitioner therefore to diagnose at a stage before the appearance of symptoms for which his advice is eventually sought is to ask the impossible. On the other hand, there are those who still preach that all cases of established phthisis have symptoms. We could wish this were true, but experience has taught us otherwise.

SYMPTOMS AND SIGNS

That the present method of approach is unsatisfactory and must deny us opportunity for the discovery of early disease in all but a small proportion of sufferers does not mean, however, that every case presenting himself is diagnosed when he should be. To found diagnosis only on the discovery of tubercle bacilli in the sputum is to wait for the late sign of ulceration of the lesion into a bronchus, and is just as culpable as to ignore the presence of nummular sputum or gross clubbing of the fingers. To delay until added sounds are heard above the collarbone is to diagnose only when at least a third of the lung is already involved. There are undoubted warnings in past and present histories of patients which nature gives and many doctors either ignore or fail to investigate. A study of the past histories of 2000 patients of Midhurst Sanatorium with positive sputum disclosed that 26.6% had an untreated or inefficiently treated hæmoptysis or pleurisy some 3 or 4 years before admission. This does not imply that these two conditions are always indicative of tuberculosis, but it does prove that large numbers of young adults do not have the expert and eliminating examination which such conditions should demand. Among similar warnings too often ignored are: cough of more than a month's duration; persistent indigestion; nausea or actual sickness with meals, especially breakfast; an unnatural lassitude, often accompanied by uncomfortable face-flushes in the late afternoon; fistula-in-ano; amenorrhœa, and erythema nodosum. There is no doubt that if patients with such complaints were referred immediately for complete chest examination and periodic review many more would be diagnosed in the earlier stages of the disease.

To many doctors physical signs in the chest have come to mean only the presence of added sounds. By its pathology the lesion cannot give added sounds until the caseous contents of infected acini break down and discharge into their accompanying bronchioles, by which time fibrosis and plastic pleurisy are developing and the patient may already be past the best stage for the simpler methods of collapse-therapy. Long before this occurs, the usual initial silent area of bronchopneumonia gives two definite physical signs in lack of movement and evidence of mediastinal shift. It imposes on the side of the disease a loss of movement far beyond its extent, so that the base lags behind that of the opposite side when the actual area of deposit is but a single subclavicular focus. Again phthisis is the chronic chest disease par excellence to produce the sign of mediastinal displacement from its earliest appearance. While the stethoscopic signs of fibrosis and the X-ray findings of tracheal and mediastinal shift are still absent, the patient with a unilateral and early lesion shows a diagnostic tension of the origin of the sternomastoid at the inner end of the clavicle on the same side of the chest, and thus warns the physician of the presence of an abnormality that requires the strictest investigation.

When added sounds do appear, they are for a considerable time slight in extent, and found only in the early *hours of the day*; their causative mucus is coughed up or absorbed hours before the usual evening consulting hour If their presence is suspected they are to be sought before the patient gets up in the morning In their actual quality they are bronchitic, in fine sibili and occasional rhonchi They have, however, two diagnostic characters which differentiate them from the sounds of simple bronchitis and thus should obviate the lesser diagnosis at a critical stage of the patient's illness First, they are unilateral and seldom heard at the base, secondly, they are, as no other such sounds in the chest, made more and more insistent with the depth of inspiration until they reach a crescendo at its very end They are therefore totally opposed to the sounds of simple acute bronchitis, which are always most evident in the first half of inspiration

---

* The Varrier Jones Memorial lecture delivered before the Halton Medical Society on Sept. 25, 1942.

Unfortunately, as we shall see upheld by the results of X-ray examination, the disease has progressed to a later stage in almost every case before it reaches expert physical examination The usual type of lesion has already signs of fibrosis and pleural thickening, and many are already showing the signs of cavitation To the stethoscope, fibrosis reveals itself in fine to coarse crepitations which have a dry quality to the ear, and are heard throughout the whole phase of inspiration They do not disappear with cough as the bronchitic sounds usually do, because they are evidence of an increase of interstitial tissue Signs of pleural thickening can often be heard in a burst of fine crepitations which accompanies the act of coughing When cavitation is present, the stethoscope usually produces a more reliable sign of its presence than can be discovered by listening for whispering pectoriloquy, coarse metallic added sounds are heard in the last half of inspiration, reaching a crescendo at the end, and remaining after cough They can be heard in many cases where whispering pectoriloquy is absent because the cavity is full or almost full of tuberculous exudate

OTHER AIDS TO DIAGNOSIS

Estimation of the sedimentation-rate of the red blood-cells may aid the diagnosis A fall beyond 10% in the micro-method or 8 in the Westergren method is suspicious, and ought to be considered in the summation of a doubtful case It is not, however, diagnostic, the cause may be some intercurernt condition, worry or psychological upset On the other hand many proved active cases with positive sputum show a fall within accepted normal limits

Sometimes an exercise-test on pulse and temperature will help The case of active disease will often fail to return a pulse-rate below 90 in five minutes, or a normal rectal temperature of 99° F in half an hour after a brisk walk for 20 minutes

The next step in investigation is X-ray examination The last 25 years have seen such great advances in equipment and technical procedure that nowadays a clear picture can be produced, while the correlation of pathological processes and their physical signs with corresponding shadows on the film has made interpretation more and more exact to the trained observer But screening and film examination are best carried out by a radiologist with experience of chest examination, a chest physician, or a tuberculosis officer

Lagging of the diaphragm and loss of translucency on the affected side are early findings in screening On the film, the first variation from normal lung shadows takes one of two main forms in the early stages of disease, according to the type of lesion This may be proliferative and fibrocaseous, or acute and exudative The former is by far the commoner in young adult tuberculosis, and usually presents a rounded area of loss of translucency in the inner or outer third of the subclavicular region on one side of the chest It is known as the "Assmann's focus" The loss of translucency is fairly even, though it tends to be densest in the centre To close inspection its edges disappear gradually into normal lung shadows, but viewing at a distance throws it into strong contrast to surrounding bronchial and vascular markings In many cases it has already broken down to cavity formation by the time of its discovery, when it shows as a well-defined annular shadow, often with a fluid level

The average early case has, however, progressed beyond the true Assmann's focus in another fashion, it has lost its rounded formation and is confused and irregular in outline, its edges, which denote advancing infiltration, merging into the shadows of consequent increased blood-supply, while its lower zone appears to be drawn out to join the increasing markings of draining bronchi that track towards the upper hilar region The background has a generalised fine loss of translucency, which is the X-ray evidence of progressive plastic pleurisy In this background, thrown into relief by distant viewing, can be seen several small scattered areas of heavier loss of translucency These are bunches of acini, organised or collapsed, and beginning to fuse They are evidence of the fibrotic character of the disease, acini that have already emptied their granulation tissue into accompanying bronchioles showing collapse, while others, unable to rid themselves of their exudate, are proceeding to caseation and organisation

Experience with mass radiography, by the opportunity it gives of studying large numbers of films, shows that there is a type of proliferative upper-zone disease that is much commoner than was formerly believed—true apical tuberculosis Here a lesion with the characteristics just described is found above the clavicle; only seldom is there present a true rounded area comparable with an Assmann's focus, although a suggestion of its previous presence can often be noted

Acute, non-fibrous, exudative phthisis is fortunately a much rarer finding Its X-ray shadows are in their ultimate characteristics not unlike those of bronchopneumonia They are alike in that they are bilateral, but where the cause is tuberculosis, they have edges which are more woolly, and they have between them areas of much more defined translucency Moreover, they are smaller, far more numerous, and tend to be confined to, or more marked in the upper and mid zones of the lung fields as against the predominantly lower zone shadows of simple bronchopneumonia, which always tend to follow the lines of the bronchial tree They are the evidence of inflammatory exudate filling the acini and caseating and disintegrating freely, because it is uncontrolled by the fibrous tissue and giant cells of the proliferative form of the disease This exudate fills the bronchi to produce the stethoscopic finding of coarse rhonchi and finer sibili of true tuberculous bronchitis, and it rapidly infects the lymph-nodes so that the hilar shadows become enlarged, matted and indistinct

MASS RADIOGRAPHY

Even from such a short description of the changes produced on an X-ray film by the earlier pathological developments of a tuberculous lung lesion, it is clear that we have in X-ray examination something quite definite to the expert eye, something which, even at its lowest valuation, is a visual indication of abnormality, calling for immediate and strict investigation In other words we have to hand a method of approach to diagnosis which can reverse the present one The doctor can seek out the patient He need not wait until the patient seeks him, driven by symptoms too often ignored until of long standing, and too often capable of other interpretations Moreover, as we shall presently see, these symptoms are too often delayed in their appearance until the disease is far past its early stages The proof for such a statement lies in the experience of the routine examination of certain selected groups of supposedly healthy subjects, which has been called mass radiography This was in its earliest experiments on smaller scales carried out as ordinary direct radiography of the chest by full-sized X-ray photographs, now it is possible to use apparatus suited to indirect or miniature radiography, whereby there is produced on a small film a reduced camera photograph of the full-size image on the fluorescent screen As against ordinary X-ray examination, it is much less costly, and it is so much faster that we can examine about seven times as many patients per day The type of apparatus using 35 mm *cine-camera* film is commonest in this country

A considerable amount of experience has been gained over the past five years from series of examinations made by direct radiography and fluoroscopy For example, large numbers have been covered among applicants for employment in the Mitcham Radio Works, the Brazil Fruit Trade and the Metropolitan Insurance Company of New York More recently there has been a large extension of the use of miniature radiography. R to he Royal Navy, the Army, the Royal Air Force, the Canadian and United States Armies and the Australian mperial Forces are passing through a scheme of mass adiography in increasing numbers

FINDINGS IN THE ROYAL AIR FORCE

Some of the results obtained in RAF and WAAF personnel (see table) will give an idea of what can be expected in examinations of the civil population Before considering them, it is well to note two special points First, all personnel in the series quoted had been through routine medical examination preceding mass radiography, n that all had been examined by National Service Boards some 6–12 months previously , in addition, all the men had had a stricter medical examination within the previous 6 months with a view to selection for special duties Those recruits therefore with declared symptoms or with physical signs found by previous examiners had already been weeded out before the remainder, the supposedly healthy, attended the Chest Radiography Sections where mass examinations are carried out Secondly, while, as already pointed out, the expert eye may be able to diagnose any form of chest disease by film examination only, the opportunities for error by individual opinion are so great and the implications to the suspect so serious that final diagnosis does not rest on X-ray interpretation alone The small film can show a variation from the normal, and when it is projected to a size about 8 in × 6 in , areas of abnormality are thrown into strong contrast with surrounding normal lung markings There the miniature film reaches its limit of usefulness—it can weed the abnormal from the normal For ultimate diagnosis, a large film, with its possibilities of greater detail, and full clinical and pathological examination are necessary in every case where an abnormality is noted Such exhaustive investigation has been carried out, with bed-observation where indicated, and no case has been considered tuberculous where there is any reasonable doubt of the diagnosis as judged by accepted modern criteria

The men in this series were X rayed by the Solus four-valve transformer set, exciting a rotating anode 'Dynamax' tube as described in a previous paper (*Lancet*, 1942, i, 609) The officer in charge is Flight Lieutenant L G Scott Of the 65 men (0 22%) considered to have active tuberculosis records show that 53 (82%) had physical signs to expert examination but 56 (86%) denied on close questioning the presence of any complaint which might be connected with their condition Of the remaining 9 the majority had usually cough, sometimes with sputum, which had been present for a few weeks only, and was considered by them to be due to a recent cold, to smoking, or to what they called "the usual morning cough which everybody has"

The women are from one unit under the charge of Flight-Lieutenant Clive The X-ray machine is of the Westinghouse condenser-discharge type, exciting a 'Machlett' stationary-anode tube

The numbers in both series are sufficient foundation for conclusions up to the age-group 25–29 The incidence of active disease is about 1 per 1000 more for women than for men at the age-group 20–24 (0 35% for men and 0 44% for women), but the incidence for women under 20 is more than double that for men (0 39% against 0 16%) Similarly among inactive cases, the incidence of disease in women under 20 is *four times* as great as among men, and one and a half times as great in the age-group 20–24, while the percentages approximate to equal in the age-group 25–29 The figures also show that among the supposedly healthy adolescent and young adult population between 18 and 24 there are some 3 per 1000 *who have unsuspected active tuberculosis*, and that more than 1 per 2000 is a potential source of infection, as he has, unknown to himself, a positive sputum The number of the population in these age-groups by the last census, corrected according to birth-rates at the end of the last war is, for England, Scotland and Wales together, some 5,000,000 The implication is obvious There are in these age-groups some 15,000 who *have unsuspected tuberculosis* , all of them require at least expert supervision and advice, and many need treatment for a period that *can be determined only* by close observation

The table gives the stage of disease found in cases considered active These cannot be strictly compared with Ministry of Health classifications in which symptoms and the presence or absence of positive sputum are considered , as already pointed out they refer to patients without admitted symptoms The classification is by extent of lung involvement only, as shown by films Nevertheless, it is a legitimate conclusion that some 25% more cases are found in the early stage of disease by mass radiography than by the present civilian methods of diagnosis Moreover it can be claimed that had the examination taken place earlier in the lives of those already in a moderately advanced stage, these figures would be better still Furthermore, all of them have a good chance of recovery in that their resistance is not yet broken , they are not yet ill with the disease

THE FUTURE

There is no proof that of those now passed as normal many will not break down in the future, immediate or more remote Periodic examination is a necessity Of the normals some are undoubtedly non-immune, and therefore not only particularly liable to infection but also especially dangerous to their fellows once they fall victims to the disease Their protection would be much increased if it were possible to extend examination to those already in the communities they are about to join , in other words mass radiography of the already employed as well as of those about to enter employment would confer a double benefit on the nation—a benefit to the individuals discovered, and a benefit to those they are liable to infect

Before embarking on any extension of mass radiography for the nation much preparatory work will be necessary. To the mind of the adult worker X-ray examination is associated with disease, and disease with economic disaster It will be hard, until he can see results for himself, to impress on him the benefits of early diagnosis. Legislation will have to come whereby he need no longer fear victimisation, the loss of his employment and the bogy of permanently reduced standards of life for himself and his family Present circumstances work against both the patient and the tuberculosis services , they hinder immediate treatment by worry and they militate against good end-results by

NUMBERS SHOWING X-RAY EVIDENCE OF PULMONARY TUBERCULOSIS

MALES

Age (yr)	Under 20	20–24	25–29	30–34	35 and over	Totals
Examined	13,431	10,795	3987	1830	85	30,130
Active	22 (0 16%)	38 (0 35%)	3 (0 08%)	2 (0 11%)	0	65* (0 22%)
Inactive	12 (0 09%)	39 (0 36%)	36 (0 9%)	20 (1 09%)	1 (1 17%)	108 (0 36%)
Total positive	34 (0 25%)	77 (0 71%)	39 (0 98%)	22 (1 20%)	1 (1 17%)	173 (0 58%)
FEMALES						
Examined	5404	2498	1096	359	182	9989
Active	21 (0 39%)	13 (0 44%)	2 (0 18%)	1 (0 28%)	1 (0 55%)	38* (0 38%)
Inactive	16 (0 38%)	18 (0 6%)	14 (1 28%)	2 (0 55%)	6 (3 3%)	56 (0 56%)
Total positive	37 (0 71%)	31 (1 04%)	16 (1 46%)	3 (0 83%)	7 (3.85%)	94 (0 94%)

* Of the cases considered active, sputum was positive in 17 males (26%) and 4 females (10 5%)

Stages by extent of lung involvement radiographically: Stage 1, males 35 (54%), females 18 (47%) , stage 2, males 21 (33%), females 18 (47%) , stage 3, males 9 (13%), females 2 (6%)

Tuberculous pleural effusion noted in 4 males and 1 female ; old tuberculous pleurisy in 3 males

Calcified nodules, calcified glands or both seen in 275 males (0 93%) and 124 females (1 2%).

Total number showing evidence of tuberculous infection males, 173 + 275 + 7 = 445 (1 51%) , females, 94 + 124 + 1 = 219 (2 2%)

In addition, 13 males and 10 females are under observation , of these, 4 males and 5 females are under 20 and 5 males and 3 *females* between 20 and 24 compelling the quiescent case to return to employment before he has attained arrest of his lesion They are an undoubted factor towards the gloomy after-histories of sanatorium-treated patients

Immediate hopes for the future control and treatment of pulmonary tuberculosis must be based on periodic mass radiography of the adolescent population, anything less comprehensive will fall short of the lessons indicated by the experience here analysed If we began now on a scheme of examination at school-leaving age and followed by annual review to the age of 30, we would cover those age-groups on which morbidity and mortality fall most heavily Initial cost would shortly be offset by the saving of vast sums of money now spent on hospital treatment of advanced cases, this money gives a disappointingly poor return in social happiness and nine-tenths of it is a loss to national economy Indeed, we must soon not only solve the problem of the early diagnosis of pulmonary tuberculosis but be ready to act on a diagnosis of early pulmonary tuberculosis

I am indebted to Squadron Leader H J Trenchard for his help in preparing the tables

PROFLAVINE POWDER IN WOUND THERAPY

G. A G MITCHELL

M A CAMB, M R C S
LIEUT COLONEL RAMC

Officers Commanding an Orthopædic Centre and a Base Transfusion Unit, Middle East Force

DURING the present war chemotherapy has been extensively used for the treatment of the wounded and appears to have been effective in reducing the incidence of infections, especially those due to hæmolytic streptococci, which were very common in the Great War but are less common in this one There has been an improvement even between two phases of the present campaign In the first Libyan offensive (winter 1940–41) the sulphanilamide drugs were employed only sporadically on the L of C, usually in completely inadequate dosage, and on admission to base hospitals the wounds were often infected with hæmolytic streptococci Thus out of 14 cases admitted to one ward from one convoy in January, 1941, 8 were infected with this organism In the second Libyan campaign (winter 1941–42) sulphonamides were given by mouth and used locally in almost every suitable case and the doses were more adequate and regular As a result the incidence of streptococcal wound infections diminished, while other infections less amenable to chemotherapy, such as those due to staphylococci, *Bacillus proteus*, *B pyocyaneus*, &c, became relatively more common But there are still some wounded men who, either in spite of chemotherapy or more probably owing to its inadequate application, arrive at the base with their wounds in a grossly infected and purulent condition In these cases the sulphanilamide drugs can do no more than prevent the spread of infection and they have comparatively little influence on the course of the local suppuration Such wounds are commonly deep or extensive, often involve bones or joints, mixed infections are almost the rule, and they have sometimes proved extremely slow to heal

These intractable wounds are a distinct problem in any hospital where large numbers of seriously wounded men are treated, and they are especially difficult in orthopædic centres where many of the worst cases are concentrated In one of these centres it was decided to try proflavine powder in their treatment, because certain experimental work to be quoted later had shown that this substance was relatively non-toxic and had a strong bactericidal effect on a great variety of organisms The first case in which the antiseptic was used was dangerously ill and the results were dramatic They have not yet been quite equalled in any other case, but since then proflavine powder has been used [illegible] of all grades of severity and the res[illegible] ently encouraging to warrant descri[illegible] ribed below may be regarded as [illegible] be expected from the use [illegible] tion used throughout wa[illegible] hate (BDH)

CASE-RECORDS

CASE 1—A corporal, aged 28, was wounded by a shell burst on Dec 8, 1941 On admission 7 days after wounding his condition was poor and his arm, which was fixed in an abduction plaster, was uncomfortable Next day, under general anæsthesia, the plaster was removed, revealing a large infected wound about 6½ in × 4 in occupying most of the left deltoid area Through this wound a large shell fragment had passed, shattering the upper end of the humeral shaft, and coming to rest in the axilla below the main neurovascular bundle Several loose bone fragments and metal splinters were removed and the wound was dressed with powdered sulphanilamide (10 grammes), covered with 'Vaseline' gauze, and the arm refixed in a plaster abduction spica Culture of the pus gave non-hæmolytic streptococci, diphtheroids and *B proteus*, so the patient was given sulphanilamide by mouth (48 g spread over 7 days) During this postoperative period his condition improved for about 10 days and then his temperature began to fluctuate between 101 and 103 4° F and pulse rate between 100 and 120 per min, while he began to complain of much pain in the shoulder

On Dec 30 (15 days after admission), under 'Pentothal' *anæsthesia, the plaster was removed and* an abscess was seen pointing below the left clavicle It was opened by one incision beneath the clavicle and a counter incision near the posterior axillary fold, a shell fragment measuring 2 in × 1 in was removed from the axilla Culture of the pus gave non-hæmolytic streptococci, *Staphylococcus albus* and *B proteus* Sulphanilamide, 10 g, was introduced into the abscess cavity and the arm refixed in an abduction plaster After operation 3 pints of blood was given by drip transfusion, and also 30 g sulphathiazole spread over 4 days

Again he improved, this time for about 3 weeks, and then his temperature began to swing up to 103° F and his pulse was consistently over 100 per min On Jan 26, 1942, another 3 pints of blood and 2 pints of glucose saline were given by drip transfusion, the plaster spica being removed and the arm merely fixed in a sling At this period his general condition was low, his appetite was poor, he was very thin, and he sweated profusely As the closed plaster *technique had failed to produce good* results, it was decided to change over to regular dressings, and all the usual drugs were tried in succession—eusol, 1/1000 acriflavine, hydrogen peroxide, sulphanilamide, and hypertonic sodium sulphate Despite everything his condition deteriorated and the discharge was profuse, coming mainly from the infraclavicular wound, which now resembled a small tea cup in size and shape (2½ in diameter × 2½ in deep)

On Feb 15, 2 g of proflavine powder was introduced through the left infraclavicular wound into the axilla The result was dramatic, the discharge drying up completely in 3–4 days and the general condition showing great improvement By Feb 28 the wound below the clavicle was healed, an astonishing occurrence *for a wound of its size* and chronicity A week later the incision near the posterior axillary fold was also healed The wound in the deltoid region also diminished in size (though less rapidly), and now (April 27) it is almost dry and is covered by a thick scab Culture from this wound still gives *B proteus* The man felt so much better that he was allowed up in a chair on Feb 25, and a week later he was able to walk The improvement has been maintained and he has recovered much strength in his upper limb, but abduction is still weak owing to the gross destruction of the deltoid muscle

CASE 2—A private, aged 27, received a bullet wound on Jan 31, 1942, which passed through the left elbow, producing comminution of the radius and capitellum On admission to a base hospital, 8 days later, his general condition was poor and the plaster on his left upper limb was stained with discharge On Feb 12, under pentothal anæsthesia, the plaster was removed and he was seen to have two wounds, an entry wound *just lateral to the* olecranon and an exit anteriorly in the antecubital fossa Both wounds were discharging freely and the elbow joint was swollen, due to septic arthritis The joint space was *opened freely*, 5 g sulphanilamide introduced and the wounds covered with vaseline gauze An abscess of the forearm was opened and drained by two incisions It was *found impossible* to straighten the elbow (with a view to applying extension) owing to the risk of hæmorrhage from the stretched brachial artery in the highly septic wound A plaster was applied with a window cut to allow free discharge, and the man [illegible] given g sulphanilamide by mouth spread over 6 days Cultures the pus gave a pure growth of hæmolytic streptococci

His general condition slowly deteriorated, and when the laster was changed on March 6 the wounds were still ischarging and the joint condition was no better In ddition he had developed a small abscess along the inner de of the arm, which was incised Sulphanilamide was gain introduced into the wounds After this operation he emained comatose for 3 days and it was assumed that this as due to the administration of pentothal in his toxic state lis blood urea at this stage rose to 42 mg per 100 c cm , is blood-culture was sterile After receiving 3 pints of lood, 350 c cm glucose saline and 700 c cm normal saline, e improved considerably, but the discharge from the elbow ontinued to be profuse Cultures of the pus still gave a rowth of hæmolytic streptococci

On March 20, under gas and oxygen anæsthesia, the plaster ras again changed The local condition showed no improve nent and pus was draining freely from the elbow and from he incisions in the arm and forearm Proflavine powder ras introduced into the elbow joint and also into the arm nd forearm wounds, about 2 g in all being employed , a resh plaster was then applied After this operation the nan stated that his elbow felt more comfortable than it had lone since he was wounded, his appetite improved, he slept nuch better and there was a noticeable change in his general ealth Within 10 days he was able to get up and since hen his condition has improved steadily

A month later when his plaster was changed the wounds of the arm and forearm were practically healed, the elbow wounds were smaller and almost dry, and now only *B proteus* could be grown in cultures

CASE 3 —A warrant officer, aged 29, sustained multiple wounds in a bomb explosion on Nov 21, 1941 His most serious injury was a penetrating wound of the right knee, with partial comminution of the lateral femoral condyle and outer margin of patella He was treated in a field ambulance within a few hours, the knee wounds were cleaned up and sutured and the limb fixed in a posterior plaster slab He did not arrive at the base until 12 days later , by then he was very ill He arrived late at night, in no state to stand operation, so his wounds were merely dressed and he was given morphia and 3 pints of blood by drip transfusion Next morning he was slightly better, and as it was clear that the right knee was infected he was given pentothal and the stitches were removed from a large lacerated wound just above the patella Pus escaped under great tension (*Strep hæmolyticus* and *Strep viridans*) , 10 g sulphanilamide was inserted into the joint, the wound was left widely open and he was fixed on a Braun's frame with skin extension Before admission he had received sporadic doses of sulpha pyridine, and after admission he was given 3 tablets 4 hourly for 4 days Then he complained of sore throat (culture gave hæmoltyic streptococci) and as his white cell count was only 9400 the chemotherapy was stopped and he was given another 4 pints of blood His convalescence was very stormy and amputation through the right thigh was considered several times, but by the end of January, 7 weeks after admission, it was clear that he was on the up grade During January successive cultures of pus at weekly intervals gave the following results (*a*) *Strept viridans* and *Staph aureus* , (*b*) *Staph aureus* and non hæmolytic streptococci , (*c*) *Staph aureus* , (*d*) *Staph aureus* and *B proteus* At this stage the discharge was very free and the temperature and pulse rate had subsided to normal, so fixation in plaster was employed

On April 24 the wound above the right knee was still large ($4\frac{1}{2}$ in × 2 in) and discharging very freely (*Staph aureus* and *B proteus*) when it was decided to use proflavine powder Approximately one gramme was introduced into the supra patellar synovial pouch the lateral side of the knee and behind the patella and the leg was fixed in a closed plaster extending from the upper thigh to the ankle A week later he was able to move around on crutches, and whereas previously the discharge had been very profuse it now dried up almost completely as judged by the condition of the plaster, which remained firm and dry When the plaster was removed a month later the wound only measured about 2 in × $\frac{1}{4}$ in It was completely healed by mid April and has not broken down since, although the patient is walking about unaided The knee is almost completely stiff, but considering that he had a severe septic arthritis the result is satisfactory, and undoubtedly the local improvement dated from the use of proflavine

CASES 4 AND 5 —Two other similar cases of septic arthritis of the knee due to war wounds might be quoted where the results were equally satisfactory and where the improvement was definitely more rapid after the use of proflavine One of these men had also a septic arthritis of the elbow which responded favourably to proflavine, and it is worth mentioning that in both cases sulphanilamide and sulphathiazole had been fully exploited before proflavine was employed

CASE 6 —A driver, aged 23, was involved in a motor-cycle accident on March 4, 1942 His only serious injury was a penetrating wound of the right knee with slight comminution of the lateral femoral condyle and patella He was operated on in an advanced hospital within 5 hours of the accident, the wound edges were excised, the skin edges only were sutured, and plaster was applied from the thigh to the foot On admission to a base hospital 3 days later the man looked ill, his toes were very blue and swollen, and he complained of much pain in the right leg and knee The plaster was split at once with immediate relief, but next day he was again in great pain, so pentothal was given and the plaster was completely removed A 4 in wound on the outer side of the knee was found to be closed with two sutures, and when these were removed thin pus escaped freely from the joint, along with pieces of sloughing synovial membrane A fresh posterolateral drainage incision was made in a dependent position, about 10 g of powdered sulphanilamide was introduced into the joint, the wounds were left completely open, and the limb was fixed in a Braun's frame with extension by skin traction He was started on a course of sulphanilamide by mouth, but this was stopped after he had received 18 g because the report on the pus (received on March 11) showed that the infecting organism was a hæmolytic *Staph aureus*

His general condition improved only temporarily after operation and 3 days later he was dangerously ill, with severe confusion and delirium and a very poor pulse When the bacteriological report was obtained on March 11 it was decided to use proflavine, and on March 12 pentothal was given and 2 g proflavine was dusted into the joint and wounds Next day he was no better, but 2 days later there was obvious improvement, especially in the mental condition, and he began to evince interest in food and in his surroundings By March 20 he had little or no pain and the discharge was so much diminished that the limb was encased in plaster This plaster was retained for 3 weeks and then was changed under pentothal anæsthesia The size of the original wound had diminished by about a half and the counter incision was practically healed , culture of the pus gave *B proteus* only Now he is much better generally and is able to get around on crutches, while the discharge has almost ceased

The improvement in this case was evident within 2 days after using proflavine, and it has been maintained, whereas the first operation at the base hospital (free drainage plus sulphanilamide) produced only temporary improvement

CASE 7 —A private, aged 27, was shot through the left wrist on March 21, 1942 He sustained fractures of the lower end of the radius and adjacent carpal bones The wounds were excised and plaster applied in a field ambulance the day after wounding On admission to a base hospital 8 days later his general condition was poor and it deteriorated in the next few days On April 2 the temperature swung up to 104° F., his pulse was 120 and he became delirious On April 3, under pentothal anæsthesia, his plaster was removed and it was clear that he had a septic arthritis of the wrist , the infecting organism was a hæmolytic *Staph aureus* Free drainage was provided, 0 75 g proflavine was introduced into the wounds and a fresh plaster applied His temperature and pulse were almost down to normal within 24 hours, his pain had gone, his delirium ceased and his general condition improved so rapidly that he was allowed up 5 days later

The plaster was changed on April 25 By then the wounds were much smaller and the discharge scanty, but hæmolytic *Staph aureus* could still be grown on culture Now, on April 27, his general condition is excellent

The improvement in this patient after the operation and the use of proflavine seemed more rapid than in cases of similar severity where this drug was not employed For examples, two officers with almost identical lesions, whose treatment began in December, 1941, made much slower progress

CASE 8 —This minor case is quoted to show that proflavine does not necessarily delay healing

A medical officer developed septic sores of his right middle and ring fingers, and the areas spread slowly despite local applications of sulphanilamide powder for 9–10 days, and administration of 12 g sulphanilamide by mouth in 4 days. He consulted one of us 10 days after the onset and it was found that he had two spreading ulcers, each 1¼ in × ⅞ in in extent, over the dorsal aspects of the proximal interphalangeal joints of the right middle and ring fingers, with enlargement and tenderness of the epitrochlear gland. Culture of the pus gave *Strep hæmolyticus* and *Staph aureus*. The dead skin was cut away, and as chemotherapy had proved unsuccessful it was decided to change the treatment. Proflavine powder was therefore applied to the raw surfaces, and next day a thin brownish pellicle had formed over the areas. Two days later pus had accumulated under the pellicle on the middle finger, so the pellicle was cut away and fresh proflavine applied. The area on the ring finger was healed within a week and the middle finger lesion in 11 days after the start of proflavine therapy. The lymphadenitis subsided pari passu with the local improvement.

Compared with many similar infections treated by other methods, the healing in this case was equally rapid, and the new skin was supple, not interfering in any way with joint movements. The interesting fact also emerged that proflavine locally was more effective than sulphanilamide in controlling a mixed *Strep hæmolyticus* and *Staph aureus* infection in this case.

DISCUSSION

Acriflavine has always been the favourite among the acridine group of antiseptics despite the fact that a number of investigators such as Albert and others (1938), Russell and Falconer (1940–41), Falconer (1940), and Manifold (1941) have all emphasised as a result of their experimental work that while proflavine is as effective as other flavine compounds in regard to its bactericidal action it is less toxic than acriflavine. It has also been shown that 2 7-diaminoacridine hydrochloride is even less toxic than proflavine (2 8-diaminoacridine sulphate), and Manifold (1941) summarises the matter thus: "Acriflavine is a mixture and presumably may vary quite widely in composition from time to time and from one manufacturer to another. It is not significantly superior bacteriostatically to either proflavine sulphate or 2 7-diaminoacridine hydrochloride, both of which compounds, particularly the 2 . 7-diaminoacridine hydrochloride, have a minimal toxic effect on the tissues. On these grounds it is felt that in spite of the wide interest in acriflavine its use as a local or internal antiseptic should be discouraged, and proflavine sulphate or more particularly 2 7-diaminoacridine hydrochloride substituted, since these are pure compounds of invariable composition and low toxicity to the tissues." Hawking (1941) found that "Applied in strong concentration proflavine will certainly prevent infection of a wound by anaerobes subsequently inserted. On reopening at the third day, wounds which had been treated with 1% or 0 1% solutions showed fairly healthy tissues and only small numbers of bacilli." He concludes that "in view of the mediocre results obtained with acridine compounds in the last war (presumably through inability to reach bacteria situated inside the tissues), the usefulness of proflavine as a wound antiseptic is probably limited." Anderson (1940) found that 1/10,000 solution of proflavine was not effective in treating wounds of mice infected with *Vibrion septique*, but 2–10 mg of proflavine powder inserted into the wounds produced as good a result as an equivalent amount of sulphapyridine, although healing was somewhat delayed.

The test of any therapeutic agent by clinical means can never approach in exactitude the results achieved under laboratory conditions where the type of wound and infection, and the factors of time and treatment can all be controlled. In clinical practice no two wounds are exactly alike as regards size, structures involved and degree of infection, while there are other possible confusing factors such as interference with blood or nerve-supply, the varying times which elapse between wounding and the institution of treatment, and variations in the actual mode of treatment before the patient arrives at a base hospital. On the other hand, results obtained in a laboratory are not always an exact guide to what occurs when the same drug is used in man, and few research workers investigating wound infections produce as severe lesions in their experimental animals as those caused by high explosives in man with their often severe destruction of bones, joints and soft tissues. In experimental work it is convenient to infect the wounds with a virulent organism which will kill all untreated animals within 24 hours, and for this reason it is not possible to delay treatment for more than a few hours after infection; there is never time to allow pus formation in the wound before treatment is started. In clinical practice wounds are infected with a great variety of organisms, which are not usually very virulent, but treatment is often delayed for several days, by which time the wound is thoroughly purulent. The presence of pus is known to have an adverse influence on the action of the sulphonamide drugs. Such considerations must be borne in mind in connexion with the subsequent discussion, because the great majority of our cases had been wounded 5–12 days before they came under our care, they had passed through three to eight different medical units before arrival, in these units a great diversity of treatments had been employed, and most of the cases were more or less heavily infected when first seen.

An extensive experience in the treatment of wounds of all grades of severity showed that certain of them were very resistant to treatment. Severe wounds of bones and joints in particular were a problem, for while some did surprisingly well others continued to discharge despite the removal of foreign bodies or sequestra and the institution of free drainage; the presence of such large discharging wounds acted as a constant drain on the strength of the patient. Every suitable case, and that included the majority, was treated by the closed plaster method; sulphanilamide, sulphapyridine and sulphathiazole (locally, by mouth and occasionally intravenously) were used according to the type of case and the nature of the infection. It has not yet been possible to try sulphadiazine except in a few cases owing to lack of supplies. Various forms of treatment, apart from routine chemotherapy and closed plaster, were tried in resistant cases, including plain saline or vaseline dressings, hypertonic salt solutions (sodium chloride and sodium sulphate), urea, eusol, acriflavine (1/1000), gentian violet, brilliant green, hydrogen peroxide, and glycerin and sulphanilamide solutions; blood transfusions whenever necessary; reduction of the carbohydrate intake, and regular courses of ascorbic acid; and physiotherapeutic methods in the form of ultraviolet light, radiant heat and infrared radiations were also employed. A number of cases, however, failed to respond despite everything tried, and it was this failure which led us to attempt a new treatment in the form of proflavine powder dusted into the wounds.

The amount of proflavine used therapeutically has never exceeded 2 g in any one case, and usually only about 0 5 g or less was employed, depending on the size of the lesion. It was introduced into cavities by means of a small Volkmann's scoop or the end of a blunt dissector, or in cases where there was an extensive wound it was dusted over the entire surface and evenly distributed with a spatula or scalpel handle. It was never employed on more than 2 or 3 consecutive occasions, 4–28 days elapsing between the applications. When used prophylactically the amount varied according to the size of the lesion, but was usually about 0 25 g, mixed with 2–5 g powdered sulphanilamide. So far the two drugs have seldom been combined during the treatment of established infections. The drug used throughout was proflavine sulphate (2 8-diaminoacridine sulphate) as we had no supplies of 2 7-diaminoacridine hydrochloride.

From the prophylactic aspect, it is impossible to assess the relative value of proflavine and sulphanilamide because the two drugs have always been used together, and then only as an adjunct to surgical measures. In 7 cases of compound fracture of the tibia and fibula and one compound fracture-dislocation of the wrist, all heavily contaminated, where early operation was combined with the prophylactic use of proflavine and sulphanilamide, none subsequently developed infection. There is no evidence that repair of either the bones or soft tissues has been delayed, and this is important, for it would be foolish to use any substance to combat a problematical infection if it interfered appreciably with healing. As regards sulphanilamide this point has already been established after its [illegible] hundreds of ases, including many infected compound fractures, where healing has been almost as rapid as in simple ases Therefore for prophylaxis sulphanilamide should always be preferred, and until further evidence accumulates as to the effect on healing it would be unwise to use proflavine as a prophylactic agent except in small doses (0 25 g or less), such small amounts may be quite sufficient to prevent the development of staphylococcal infections

We are on surer ground when we come to discuss the therapeutic effect of proflavine in cases of established infection Where staphylococci are the infecting organisms proflavine has proved more effective in controlling or eliminating the infection than any other drug or method of treatment—e g , sulphathiazole—so far tried It should be made clear that proflavine has never been used except as a local application Sometimes the staphylococci disappear entirely, but even if they persist both the local and general condition improve after treatment When some operative procedure is combined with the use of the powder, it is impossible to tell how much of the improvement is due to the surgeon and how much to the drug , but by contrast with other similar cases we feel certain that those in which proflavine was used did the better Thus two cases of septic arthritis (cases 6 and 7), one of the knee and the other of the wrist, both infected with hæmolytic *Staph aureus* and both dangerously ill, improved rapidly after the institution of free drainage and the instillation of pure proflavine Doubtless the operation was the chief factor in the improvement but by comparison with other cases of septic arthritis it seemed to be more rapid than usual and it was maintained Case 1 is important in this respect because the proflavine was the only measure employed immediately before his dramatic change for the better

The benefits of proflavine treatment are not confined to patients with staphylococcal infections Indeed many cases have shown improvement irrespective of the type of infecting organisms, and when used in a highly concentrated form proflavine appears to be active against all the common pyogenic organisms *B proteus*, however, appears to be more resistant to its action than any of the other common organisms, and this bacillus has an annoying habit of appearing in wounds despite every precaution to prevent infection , fortunately it does not appear to have a high toxigenicity It will be noted also that proflavine may produce good results in cases which have failed to respond to sulphanilamide and other drugs of this series It is not suggested that proflavine should supplant sulphanilamide and its allies as a prophylactic or therapeutic agent, except perhaps in cases where the infection is known to be staphylococcal In such cases local application of proflavine, with the general administration of sulphadiazine or sulphathiazole, may be found the best combination

The effect of proflavine in drying up a wound is sometimes remarkable, and often a thin eschar forms over the wound, not dissimilar in consistence to that produced by tannic acid in burns, while, just as in tannic acid therapy, pus occasionally forms under the pellicle When the discharge is very profuse this process is less liable to occur In some cases a brownish scab forms over the wound which is slowly raised from the surface by the formation of a gelatinous material beneath, possibly coagulated serum In 5 or 6 out of the 80 cases of this series where proflavine has been employed there has been no improvement Proflavine has often been employed in conjunction with the closed plaster technique, and in cases where the wound is not so covered dressings are performed as infrequently as possible—every fourth to seventh day depending on the amount of discharge

Several of the cases quoted supply evidence that, contrary to expectations derived from experimental work, healing is not apparently delayed, but in this connexion one case should be quoted An officer with a chronic tibial abscess, the sequel of a gunshot wound, had “ saucerisation ” performed The extensive bone cavity was filled with a mixture of about 10 g sulphanilamide and 2 g proflavine, and after 6 weeks practically no new bone had formed Ten weeks after the operation new bone was forming and the cavity was healing, but the process had been slower than usual Whether this was the result of using the chemicals or whether it was due to other causes we cannot tell Against this case we can place the undoubted fact that in 79 cases with bone, joint and soft-tissue injuries no appreciable delay in healing has occurred

Most patients find the dressing painless and unirritating, although a few complain of a slight burning sensation which soon abates No general toxic manifestations, such as skin eruptions, albuminuria, jaundice, nausea, vomiting or headache, have been encountered

SUMMARY

Proflavine is much less toxic than acriflavine and it has been used in pure form as a dressing for certain intractable wounds

So far it has been used therapeutically in 80 cases, with beneficial results in almost every case

Where staphylococci are the infecting organisms, proflavine has proved more efficient in controlling or eliminating infection than any other drug so far tried, and many cases with mixed infections have also responded well

With the possible exception of one case, no interference with healing has been noted

Most patients find the dressing painless, and no general toxic manifestations have been noted

Our thanks are due to Colonel H D F Brand, OC 15th Scottish General Hospital, for permission to publish this article, to the sisters and orderlies in the orthopædic wards and theatre who have assisted in the clinical work, and to the staff of the pathological laboratory who have examined and reported on so many specimens

NICOTINIC ACID IN TREATMENT OF ANGINA PECTORIS

F J NEUWAHL
M D BERLIN, L R C P E, PH D ERLANGEN
PHYSICIAN TO THE LAW NURSING HOME, ROCHDALE

THE use of nicotinic acid in the treatment of pellagra has achieved much prominence in the last few years, especially in the United States In view of the advantages claimed for this substance in pellagrous psychosis, it was decided that a trial of its possibilities should be made with patients whose mental symptoms were of a similar, though not completely corresponding type These investigations have led to the present work Six cases of angina pectoris have been treated with nicotinic acid, and the results in this series appear to be remarkably uniform and lasting

Administration of the drug by mouth caused in several cases a noticeable decrease in number and severity of attacks, but in others the effect was transient, possibly because of interference with absorption or interaction of chemical substances in the gastric secretion Moreover the drug could not be discontinued without relapse, and the treatment appeared therefore to be merely symptomatic Intravenous administration heightened the efficacy of the drug It was therefore decided to discard tablets of nicotinic acid, in order to obtain equal conditions for each case and an evaluation of the treatment after its discontinuation A drip infusion of a 0 05% solution of nicotinic acid was chosen to overcome differences in susceptibility to nicotinic acid , isotonic solutions are rapidly absorbed, giving sufficient concentration of the medicament in a short time One infusion containing 100–300 mg produced as a rule a remarkably beneficial result, which was maximal after 12–24 hours Further infusions seemed to cause a definite stabilisation in the condition of the patients, who became free from anginal attacks after several weeks, the worst cases reacting best In most cases it was considered sufficient to give six infusions, so that treatment finished after approximately 3 weeks, though in some cases more treatment may be required We now have 6 cases showing complete or almost complete regression of symptoms of angina pectoria over a period of 3–7 months after completing the course of treatment, 3 cases have actually resumed heavy manual work

CASE-RECORDS

CASE 1 —A builder, aged 65, who had always been healthy until the first attack of substernal pain 2 years ago Continued to work with the help of nitroglycerin tablets The pain, constricting and burning in type, radiating into both arms, became gradually worse, especially in cold weather In autumn, 1941, frequent attacks of pain caused him to retire from work No dyspnœa at rest, but slightly breathless on exertion Physical examination of the heart did not reveal any enlargement, sounds faint, no murmur, resting BP 120/80 mm Hg Pulse regular, 84 per min, radial and retinal vessels appeared normal He was tested to ascertain the amount of effort necessary to cause anginal pain, 17 steps of the usual type of staircase caused intense pain, with BP 180/110 mm Hg, pulse 110 Treatment started Feb 2, 1942 Next day reduction in pain was noticed, and patient felt able to walk a short distance, after the 8th infusion on March 21, he could dig a plot 10 ft by 20 ft in his garden in less than an hour without pain After the 10th treatment he was tested again, 193 steps of the same staircase were mounted, going very quickly up and down This exercise was interrupted because no pain was felt, and it appeared unnecessary to continue the test When re examined on July 7, 1942, he was doing the work of a man in good health, did not take any drugs, and had no pain, though he carefully abstains from sudden exertion

CASE 2 —A cotton spinner, aged 50 No history of serious illness Started to become breathless on exertion 8 months ago, 2 months later had acute attacks of heartburn and indigestion, especially after an effort He took alkaline powders, and they helped to a certain extent Again 2 months later, after a brisk walk, had intense substernal pain and had to stop This pain forced him to give up work, because it reappeared frequently from that time after exertion Examination on March 10, 1942, showed no dyspnœa at rest, but breathlessness on exercise No signs of congestive failure or cardiac enlargement, heart sounds faint Systolic murmur over base of heart No abnormality of peripheral and retinal vessels Pulse 90 per min Resting BP 130/90 mm Hg Wassermann reaction negative No signs of renal defect On mounting a staircase, 38 steps caused an anginal attack, which forced him to stop BP shortly afterwards, 170/70 mm Hg, pulse 96 per min Nine minutes later, at 4 24 PM, infusion was started, BP fell from 135/75 to 118/80 mm Hg Pulse rate fell from 90 to 68, but later remained around 78 per min Infusion finished at 5 40 PM At 5 45 the patient was retested, 95 steps of the same staircase were mounted very quickly Became breathless, but did not experience any pain at the end of this exercise Next day was tested by a walk of ¾ mile, slightly uphill Became very breathless but felt no pain Three infusions were given He felt fit after this treatment, and has since resumed work Re examined on July 24, 1942 Has been employed at his former job for the last 3½ months Does hard work every day, but abstains from sudden exertion, has not experienced any pain, and feels extremely fit

CASE 3 —A farm hand, aged 27, with congenital syphilis No external signs of syphilis Never been seriously ill and is in fine physical condition WR ++ Examination of CNS entirely negative, no signs of heart failure, no dyspnœa on exertion, no enlargement of heart and no murmur, second aortic sound slightly accentuated Pulse regular, 76 per min, BP 130/80 mm Hg Came under observation on account of unbearable pain in chest, radiating down inner side of left arm, and once into both arms First attack occurred in July, 1941, after effort On two occasions pain became unbearable, and he had to lie down and keep immobile for 5 minutes before it ceased Left arm was sore during and after attacks of pain, which usually lasted 4–5 min, unless interrupted by a nitroglycerin tablet Received antisyphilitic treatment, starting with small doses of iodine and bismuth Later neoarsphenamine was given and well tolerated No change in the anginal syndrome Treatment with nicotinic acid started Jan 23, 1942 Soon after first infusion reported a decrease in pain during attacks After three infusions took up work again, and has remained a very active worker Has no pain except when starting a sudden and sustained effort Even then he has not to stop but only to slow down to get relief It seems evident that the orifices of the coronary arteries have been narrowed by a syphilitic process and the anginal pain therefore returns when the structural changes do not allow a sufficient amount of blood to enter or to leave the coronary system

CASE 4 —A bus driver, aged 58 Was forced to give up work 5 years ago on account of mitral stenosis Very dyspnœic on slightest exertion, has a persistent irritating cough Radial vessels slightly harder than normal Pulse irregular (frequent extrasystoles) At times pulse grossly irregular, due to transient auricular fibrillation BP 180/110 mm Hg In 1938 experienced first substernal pain Afterwards attacks came on at any time after slight exertion and after food When mild they had the character of acute indigestion and fullness in the chest, when stronger a burning pain radiated into both arms, especially down the inner side of left arm First treatment Feb 4, 1942 Morning after infusion was able to rise without pain and to start dressing immediately, instead of sitting on the edge of the bed to overcome the first anginal attack Received six infusions within 3 weeks Has had no further anginal attacks Now works in his wife's business, can walk 5 miles, and is generally active and independent

CASE 5 —A widow, aged 62 Was a cotton spinner until 4 years ago, since when has not worked because of pain in chest, which became gradually worse, was burning in character radiating into left arm Pain easily caused by short walk or by exercise after a meal Worse in cold weather No dyspnœa at rest, but breathless on exertion Physical and X ray examination show only moderate enlargement of heart, *but well marked dilatation of aorta* Blowing diastolic murmur in aortic area Water hammer pulse Radial and retinal vessels slightly tortuous WR negative Resting BP 135/85 After first infusion on May 4, 1942, much better nights Acute attacks of pain disappeared entirely, but still felt oppression in chest during long walk After third infusion this oppression also disappeared Now undertakes much more exercise, and has regained her old confidence Tested on a walk, approximately 1 mile, going slightly uphill no pain but tired and breathless

CASE 6 —A gardener, aged 60 Illness started in May, 1941, with attack of breathlessness on exertion Stayed off work for a week Shortly afterwards had acute attack of pain in chest while lifting window of a greenhouse Attack was severe, lasting for a long time, and only passed slowly away on sitting down Left arm remained sore for long time afterwards Since then pain has frequently recurred Only caused by exertion, is continuous, and passes away when he rests It is of burning and gripping type Not breathless at rest, no signs of cardiac failure or of a vascular lesion Heart shows neither clinical nor X ray signs of enlargement Peripheral and retinal vessels slightly thickened and tortuous WR negative Resting BP 165/90 mm Hg Pulse rate 84 Average number of steps of usual type of staircase required to produce pain was 60 BP afterwards 210/110 Pulse rate 120 Abnormally breathless First treatment March 19, 1942 Improved considerably Retested after third infusion on May 27 Amount of exercise tolerated now limited by breathlessness, not by pain Has had no anginal attack since first infusion, sleeps much better, has taken up light work again, and regained some of his old confidence, though he still abstains from exertion

PHARMACOLOGY

Most of the clinical work with nicotinic acid, apart from pellagra, was based on its vasodilating action, which appears to be independent of its action as a vitamin This effect is, however, of short duration, and elimination of the drug by the body is probably completed within a few days To account for the lasting results in the foregoing cases, we have compared the action of nicotinic acid with that of histamine, both of which have a heterocyclic ring —N— with a substituent group in beta position Though there is no obvious chemical relation, a resemblance between the pharmacological action of histamine and nicotinic acid was found

The well-known reactions following a subcutaneous or intravenous injection of 0 1 mg of histamine sodium phosphate can be nearly reproduced by a 50–500 times larger quantity of nicotinic acid The effects of such a dose of nicotinic acid are as follows

On smooth muscle —No effects in normal persons, except in two who complained of severe cramp like pain in the epigastrium after 5 mg of nicotinic acid intr A delayed action was noted in 3 asthmatics, 2 reported severe asthmatic attacks after taking 50 mg of nicotinic acid by mouth, the third, who received 100 mg by intravenous infusion, reacted with a violent attack 15 hours later. In 4 other cases, however, the effect appeared so beneficial that ephedrine was replaced by nicotinic acid.

On secretion.—Rise in the volume and acidity of the gastric secretion after 50 mg of nicotinic acid intravenously. In 2 patients with a fasting achlorhydria, hydrochloric acid appeared in increasing amounts, though the effect was not so great as that produced by histamine. Sweating was never noticed, even with doses of 600 mg, though Forgan (1939) mentioned this action.

On cerebrospinal fluid.—Slight rise in pressure.

On blood vessels.—Moore (1940) reports that nicotinic acid produces vasodilatation and increased blood flow in the brain and spinal cord of the cat. Furtado[1] confirmed the cerebral vasodilator action of nicotinic acid. Adams and Robinson (1941) utilised the vasodilatory effect of nicotinic acid with success in 7 cases of trigeminal neuralgia. A headache similar in type to that following an intravenous injection of 0·1 mg histamine could be produced in 4 patients. It was necessary to give the infusion rapidly. A sense of fullness is first felt, which increases to a sharp headache.

On the heart and blood vessels.—The responses to a given dose vary in different subjects, and in the same subject from day to day. Because of these variations, every observation has been followed by several control tests, to test and possibly to eliminate the effect of a modifying factor on pulse rate and blood pressure. Healthy adults are far less affected than patients, especially those with hypertension. Usually the effects begin within ½–2 min of the start of the infusion, simultaneously with the flushing of the face and the upper part of the body, the systolic blood-pressure falls 5–40 mm Hg. The diastolic pressure was little altered, but sometimes rose a few mm. The striking fact which emerges from these observations is the difference between histamine and nicotinic acid in their action on the heart rate. The former causes a distinct increase, the latter in most cases an equally distinct slowing. The reduction coincides in each case with a fall in blood-pressure, and this relationship cannot be accidental, because it occurred in more than 100 infusions and 40 different patients, though in an equal number of normal controls the results were less definite.

DISCUSSION

The degree of central vagal tone, which exerts a prevailing influence on the heart-rate, runs parallel with the height of the blood-pressure. Nitrites, like histamine, cause a well-marked fall in blood-pressure, and thereby an acceleration in pulse-rate, the action on the vagal tone being a sequel to the change in blood-pressure, and only to a slight degree a direct action on the vagus itself. The question therefore remains how nicotinic acid can cause a fall in blood-pressure, and at the same time a slowing of the heart-rate. One possibility is that nicotinic acid causes a vagal stimulation. This view however implies that production of acetylcholine follows the administration of nicotinic acid, because the vagus produces its effect on the heart by liberating free acetylcholine at its endings. Comparison of nicotinic acid and acetylcholine, by measuring their effect on the frog's heart and rectus abdominis, shows that nicotinic acid has scarcely any effect, and a physiological relationship between the two substances appears unlikely. A second possibility is that nicotinic acid causes a rise of pressure in the cerebral arteries and an increased blood-supply to the brain. Furtado[1] quotes C. D. Aring, who found that nicotinic acid produced an increase in cerebral circulation, accompanied by intense cerebral congestion. This rise of pressure could bring about inverse changes in the arteries of the rest of the body, and, accompanied by reflex cardiac inhibition, would account for the fall in blood-pressure and the slowing of the heart-rate.

SUMMARY

A series of 6 cases of angina of effort have been treated by intravenous infusions of nicotinic acid. Subjective and objective evidence of continued improvement followed and this has been maintained during the last six months. The action of nicotinic acid on blood-pressure and heart-rate was constant in almost every case, both being reduced.

DIAGNOSIS OF COMA IN CEREBROSPINAL FEVER WITH DIABETES

LESLIE COLE, M.D. CAMB., F.R.C.P.
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE

WHEN two diseases, each a cause of coma and each urgently needing specific treatment, simultaneously affect the same patient, accurate diagnosis of both is of extreme practical importance. In a series of 20 cases of meningococcal meningitis treated during the last fifteen months at Addenbrooke's Hospital 4 showed signs of diabetes on admission, 3 of these were comatose and 1 precomatose. These are recorded to emphasise the fact that the two conditions may occur together and to illustrate the difficulties and importance of making the double diagnosis at once.

CASE-HISTORIES

CASE 1.—A woman of 19, admitted comatose on Feb. 23, 1941, with a diagnosis of meningococcal meningitis. The doctor who sent her in did not know she had been treated for diabetes and this was discovered on admission. She had *had it since the age of 11, had been taking 30 units of insulin* daily and had had six attacks of diabetic coma. On admission she was comatose and dehydrated with sighing respiration, a smell of acetone in the breath, peripheral circulatory weakness, reduced tension of eyeballs, dry furred tongue, head retraction, Kernig's sign, sluggish reflexes, and blood-pressure 100/75 mm Hg. Temperature 97° F, pulse rate 130, respirations 24. Urine specific gravity 1040, orange reduction with Benedict's test, Gerhardt's and Rothera's tests strongly positive. Blood sugar 0·44%, 0·62% five hours later. Cerebrospinal fluid purulent, meningococci present in large numbers. Insulin, 280 units, given in twenty-four hours (220 units in first twelve). Rectal and intravenous drip saline with glucose. Subsequently insulin 30–60 units daily. Sulphapyridine, 7 g in first twenty-four hours, total, 51 g in ten days. She recovered from coma on third day after admission. Recovery uneventful. Discharged on March 19, 1942, on carbohydrate, 200 g daily, and insulin, 30 units twice daily.

CASE 2.—A woman of 50, admitted comatose on Feb. 25, 1942. She had suffered from diabetes mellitus for 11 years and had been taking protamine zinc insulin, 12 units every morning. On Feb. 23 she retired to bed with pains in her legs and on the day of admission was found unconscious though very restless. No insulin was given. On admission she was comatose and restless with sighing respiration. No dehydration, no smell of acetone in breath, no head retraction or Kernig's sign. Tongue moist, good circulation, blood-pressure 160/110 mm Hg. Deep reflexes present and equal. Plantar responses extensor. Temperature 102° F on admission falling to normal, pulse rate 100, respirations 24. Urine specific gravity 1040, Benedict's test, orange reduction, Gerhardt's and Rothera's tests strongly positive. Blood sugar 0·37%. A tentative diagnosis of cerebral thrombosis and diabetes mellitus was made, unfortunately lumbar puncture was not done until twenty-four hours after admission, when purulent CSF was found, with meningococci in pure culture. Insulin, 100 units, was given in the first twelve hours, with rectal salines and glucose and some fluids and glucose by the mouth. On this the blood sugar fell to 0·17% and the ketone bodies in the urine disappeared although sugar persisted. The coma and general condition did not improve. Twenty four hours after admission treatment by sulphapyridine was begun and 12 g was given daily for the next forty-eight hours, mainly intramuscularly. The patient's condition did not improve and she died on Feb. 28.

CASE 3.—A woman of 40, admitted in a drowsy state on March 13 with a two days' history of occipital headache, dimness of vision, pains in the back and retching. She had had a sore throat, cold and cough for five days. On admission she was very drowsy but could be roused with difficulty to answer questions. Stiffness of neck, Kernig's sign and occipital headache present. Blood-pressure 140/95 mm Hg. Temperature 100° F, pulse rate 120, respirations 20. Urine sp. gr. 1030, Benedict's test, yellow reduction, Gerhardt's and Rothera's tests strongly positive. Blood sugar 0·14%. CSF purulent with meningococci in large numbers. March 15, sugar tolerance curve: resting 0·14% (50 g glucose given), 0·21, 0·24, 0·22, 0·16, 0·15. Glucose, 2 g, passed in specimens one and three hours after glucose. Sulphapyridine, 12 g, was given in first twenty four hours, 52 g in eight days The glycosuria persisted intermittently for four days and then ceased May 7, sugar-tolerance curve fasting blood sugar 0 07%, 0 18, 0 16, 0 06, 0 06, 0 06 No glycosuria Discharged well on April 10

CASE 4—A woman of 26, admitted in coma on March 5, 1942, with a seven days' history of sore throat, pains in the back and aching legs, and a severe headache with nausea for twenty four hours On the morning of the day of admission she was found unconscious in bed She was comatose on admission, with slight cyanosis, cold extremities, shallow breathing and smell of acetone in breath, Left plantar response extensor Blood pressure 120/75 mm Hg Temperature 102° F, pulse rate 160, respirations 20 Urine. Sp gr. 1026, Benedict's test, yellow reduction, Gerhardt's and Rothera's tests strongly positive Blood sugar 0 26% CSF purulent, with meningococci in small numbers and a scanty growth of meningococci Insulin, 30 units, in first twelve hours followed by 10 units twice daily for the next nine days Intravenous glucose saline drip Sulphapyridine, 18 g intramuscularly in first thirty six hours, total, 52 g in ten days Nasal feeds and daily lumbar puncture while comatose Partial consciousness returned on March 7 and she became fully conscious on March 9 On March 12 she developed a left facial weakness which had almost cleared up on discharge Intermittent glycosuria persisted until March 9 March 20, sugar tolerance curve fasting blood sugar, 0 08%, 0 11, 0 14, 0 13, 0 12 No glycosuria Discharged well on April 4

DISCUSSION

Ward and Driver[1] describe a case of meningococcal meningitis starting as diabetic coma in a man of 19 Their patient was admitted comatose with flaccidity of all four limbs, a smell of acetone in the breath, glycosuria (3%) and ketonuria The blood-sugar on admission was not recorded After 110 units of insulin and 75 g of glucose in five hours he recovered consciousness, signs of meningitis then appeared and were confirmed by lumbar puncture Treatment with sulphapyridine was then begun and recovery was uneventful They suggest two possible explanations of the cause of the hyperglycæmia, pressure on the floor of the fourth ventricle causing the liver to yield up its glycogen, as in the animal experiment by Claude Bernard, or reduction of insulin output owing to the effect of toxæmia on the islet tissue They favour the first view, and in support of it cite the fact that in this case there was a left facial paralysis, probably due to involvement of the nucleus of the seventh nerve. Twenty-four days after the onset there was no evidence of diabetes as shown by a normal urine and sugar-tolerance curve Hunter[2] records another similar case of meningococcal meningitis in a child of 4 years in whom the combination of coma, ketonuria and glycosuria at onset led to the provisional diagnosis of diabetic coma. Here the glycosuria cleared up after sugar and 15 units of insulin, and the sugar-tolerance curve was subsequently found to be normal

Of the 4 patients reported here, case 1 is an example of diabetic coma precipitated by meningococcal meningitis in a known diabetic Here the clinical signs of diabetic coma were typical There was well-marked dehydration, peripheral circulatory failure, low blood-pressure, a smell of acetone in the breath, pronounced ketonuria and glycosuria and a high blood-sugar There were also unmistakable signs of meningitis The immediate treatment of both conditions was urgent, it was given and the patient recovered Case 2 is an example of meningitic coma in a known diabetic There was a long history of diabetes but the clinical picture was not at all typical of diabetic coma for there was no dehydration, the peripheral circulation was good, the blood-pressure high and there was no acetone in the breath There was also no evidence of meningitis except coma. Here the diabetic factor in the coma, which was probably small, was treated at once but there was delay in treating the meningitis and the patient died Cases 3 and 4 are examples of a transient diabetic condition secondary to cerebrospinal meningitis similar to those described by Ward and Hunter and like theirs clearing up completely as the meningitis was cured In such cases it is important not to overtreat the diabetes or overlook the meningitis. In case 3 the symptoms and signs of meningitis were so definite that diagnosis was clear and the diabetic symptoms were slight and did not need treatment In case 4 diagnosis was much more difficult The complete absence of signs of meningitis, poor peripheral circulation, altered breathing and smell of acetone in the breath, with glycosuria, positive Gerhardt's test and blood sugar of 0 26% were all suggestive of diabetic coma, though 0 26% was very low for such severe coma Against this diagnosis was the comparative absence of dehydration, the relatively high blood-pressure of 120/75 mm Hg, and the rapid response of the ketonuria, glycosuria and blood-sugar to glucose, fluids and a small dose of insulin. In this case it is clear that the main cause of coma was meningitis but the ketosis was probably an additional cause and its control by small doses of insulin may have helped towards recovery Here also as in Ward's case there was a left facial palsy

Meningococcal meningitis complicating true diabetes is probably rare, while a transient glycosuria and ketonuria in the early stages of meningococcal meningitis is not uncommon In all such cases the relative importance of the diabetic and meningitic factors must be accurately assessed since the right treatment depends on this Diagnosis is often made more difficult by the fact that patients in coma can give no history and there may be none available, this confirms the necessity for a diabetic always to carry a card stating the diagnosis and insulin dosage. Mistakes will be avoided if the association of the two conditions is remembered, if the clinical features of the coma are carefully considered, and if a lumbar puncture and blood-sugar are done at once

SUMMARY

The association of meningococcal meningitis, diabetes and coma is illustrated by four cases · (1) diabetic coma in meningitis, (2) meningitic coma in diabetes, (3) two cases of meningitis with transient diabetes, one comatose and the other precomatose

I wish to thank Dr C H Whittle for the pathological and Dr N R Lawrie for the biochemical investigations of these patients

IMMUNISATION WITH T A B IN AN OUTBREAK OF PARATYPHOID FEVER

E CUNNINGHAM DAX
B SC LOND, D P M
MEDICAL SUPERINTENDENT
AT NETHERNE HOSPITAL,
SURREY

DORIS M STONE
M D LOND, D P H
BACTERIOLOGIST TO THE
EMERGENCY PUBLIC HEALTH
LABORATORY, SECTOR 9

AN outbreak of paratyphoid fever presenting some interesting features occurred in Netherne Hospital in June, 1940 The epidemic was limited to one villa containing 80 patients, a mixture of mental defectives and cases of secondary dementia, 55 were from time to time incontinent and unclean in their habits

The villa is self-contained and staffed by 8 nurses who sleep on the premises Food is not prepared there but is supplied from the main kitchen and is identical with that served to patients in the rest of the hospital on arrival at the villa it is heated and served out in the kitchen The milk and water supplies are identical with those to the main building Two airing gardens are used, one of which had a fairly large patch of grass This has since been replaced by asphalt as it was thought that an incontinent carrier might have fouled the grass and thus infected a garbage eater

The first case developed on June 7 An idiot, who was known to eat any rubbish available, became ill with diarrhœa, vomiting and pyrexia She was nursed in a side room but was not strictly isolated Next day a second patient was found to be ill, but since she showed no gastro-intestinal symptoms the nature of the illness was still unsuspected On June 12, however, 5 other patients developed diarrhœa, vomiting and a rise in temperature Strict isolation was then practised, but during the following six days 12 further cases developed, the last on June 27

The ages of the patients ranged from 3 to 60 years, but most of them were in their teens ourse of the lness was variable In some cases the temperature ettled in two or three days and the vomiting and iarrhœa were mild, in others the temperature remained ationary at about 102° F for two to three weeks, astro-intestinal symptoms were acute and the general ondition poor The spleen was palpable in 3 cases, and a fourth reached half way down to the umbilicus rops of rose spots were found on the chest and abdomen about a third of the patients, 2 cases developed neumonia Out of a total of 19 cases 4 died, all 4 ere idiots and 2 were so difficult to manage that they ere on a chloral and bromide mixture at the time ll the patients in the villa were kept under observation, nd morning and evening temperatures were taken On une 26 all except those with clinical signs were given 2 c cm of TAB vaccine (PDCo), and this was ollowed by 0 5 c cm and 1 c cm at weekly intervals After the first dose of vaccine, one patient developed a mild pyrexia which lasted for a few days, and she has herefore been classified as a case, but otherwise no urther cases occurred

---

[1] Ward, C W and Driver, A A *Lancet*, 1940, ii, 228

[2]. Hunter, R R. *Ibid*, 1940, ii, 604

Before June 30 the fæces and urine had been examined nly in patients showing clinical evidence of disease, but from then onwards weekly routine examinations were made on all the occupants of the villa At the first survey 23 patients were found to be excreting *Bacterium paratyphosum B* in the fæces without showing any symptoms, and they were regarded as subclinical cases and isolated In these patients it was impossible to determine the date when infection had begun, and the period over which they carried had therefore to be calculated from the time when the first examination was made Cultures from the fæces showed that of the 15 clinical cases which survived 10 were free from *Bact paratyphosum B* within six weeks, 2 patients carried the organism for nine to ten weeks, one for at least thirty-six weeks, and 2 others are still carrying after an interval of more than 2 years

Among the 23 subclinical cases, 14 were free from *Bact paratyphosum B* within two weeks of the first examination, 4 within four weeks and 3 within eight weeks One patient is still carrying and another patient, after remaining negative for fourteen months, suddenly became positive and has remained so

The source of the epidemic has not been determined Routine examination of the milk and water supplies was carried out and the excreta of the entire kitchen staff were examined, with negative results Since the epidemic was strictly limited to the one villa it was considered most likely that one of the recent admissions to this block was an undiagnosed carrier Only 4 patients had been admitted within the preceding six months Of these, 2 developed symptoms of enteric infection and the infecting organism was isolated from the stools In both the fæces became negative within a fortnight and have remained so during all subsequent examinations A third patient was found on one occasion to be carrying *Bact paratyphosum B* in the stools, but also became permanently negative within a few days The fourth patient has never shown evidence of the disease nor have cultures of the fæces or urine ever yielded *Bact paratyphosum B* It therefore seems unlikely that any one of these 4 was instrumental in originating the outbreak under consideration

One other possibility relates to a patient who was admitted into the villa a year before the epidemic She was transferred from the main block of the hospital, and it was known that enteric infection had occurred there more than once some years previously When the fæces of contacts were first examined she was found to be carrying *Bact paratyphosum B* and has been carrying continuously ever since in spite of drastic treatment She may have been a chronic and undetected carrier when transferred from the main block, but if so it is difficult to explain the interval of a year which elapsed before symptoms broke out among her fellow patients

BACTERIOLOGICAL TECHNIQUE

Throughout this investigation all specimens of fæces and urine were sent to the laboratory on the day they were taken Once the nature of the epidemic had been established, the routine method of examination used was as follows

A thick suspension of the fæces was made in peptone water and was plated directly on to MacConkey's medium A drop of this suspension was also added to a tube of sodium tetrathionate broth, and to each of 7 tubes of peptone water containing brilliant green in dilutions of 1 in 70,000 up to 1 in 1,000,000 Next day the MacConkey plates were examined for the presence of non lactose fermenters and these were identified in the usual way The brilliant green and tetrathionate cultures were plated out on MacConkey's medium and examined after twenty-four hours' incubation Urines were spun down and the deposit plated directly on to MacConkey's medium

Our results were similar to those obtained by other workers and require little elaboration Of the first 82 positive fæces examined only 34 yielded the organism on direct plating In the remaining 48 cases, the organism was isolated from both the brilliant green cultures and the tetrathionate broth in 24 instances, from brilliant green cultures only in 14, and from the tetrathionate broth alone in 10 There is thus a strong case for the use of all three methods in routine examination

Examination of urines yielded consistently negative results, but the difficulty of obtaining catheter specimens from these patients made it impossible to carry out an extended series of investigations The antibody response was not determined since vaccine was given to all the occupants of the villa early in the outbreak

DISCUSSION

The proportion of those exposed to infection who either developed the disease or became temporary carriers is surprisingly high At the first survey, 42 patients out of 80 were found to be carrying *Bact paratyphosum B* in their stools, 19 of those were typical cases, the other 23 gave no clinical evidence of the disease This figure may well have been higher since routine examination of the stools was not begun till about three weeks after the first case had occurred The closed nature of the community and peculiar facilities for the spread of infection afford an obvious explanation of the high proportion obtained

The ratio of transitory carriers without signs to typical cases of the disease is higher than would have been expected Klinger (1909), however, found that of 211 transitory carriers only 92 gave a history of previous enteric infection The remaining 119 had never to their knowledge had the disease It seems possible, therefore, that during an epidemic the number of subclinical cases who carry the infecting organism may exceed those developing symptoms Most of the 23 cases we detected may belong to this category On the other hand, it is known that enteric organisms may be isolated from the stools during the incubation period and that this period may be as long as 38–40 days (Miner 1922) It is reasonable therefore to consider that some of the 23 carriers were potential cases

There is a tendency for epidemics to limit themselves spontaneously. Most cases occur in the first few weeks after the appearance of the primary case, and there is then a gradual decline The epidemic under consideration, however, ceased abruptly less than three weeks after the development of the first case, and this in a community which must continuously have been open to reinfection Did mass immunisation in some way limit the spread of infection and the development of the disease? Vaccine was given to all the patients without clinical signs, including the 23 carrying *Bact paratyphosum B* in the stools No fresh cases developed, and of the contacts known to be carrying the infecting organism only one developed a mild pyrexia suggestive of an abortive attack

It is an accepted fact that development of immunity, as indicated by the appearance of antibodies in the serum, does not begin for about five to six days after the first immunising dose, and is probably not appreciable for another seven to ten days, thus it seems scarcely credible that the sudden cessation of the epidemic can have been due to the inoculation It is worth while comparing our experience with that of Ramsey (1935) who carried out similar inoculation of household contacts and compared the incidence of cases among this group with that in an uninoculated group He found that the observed number of cases developing among contacts who had received 3 doses of vaccine was only a quarter of the expected number, and that even in contacts who were still in the process of being immunised the reduction amounted to a half He does not draw any conclusion from this latter result, on the grounds that the numbers concerned and the differences obtained are too small to be statistically significant Our results also refer to small numbers and we have no control group with which to compare them, so that we also do not feel justified in drawing definite conclusions Taken in conjunction with Ramsey's figures, however, it seems that even after the first dose of TAB there is a tendency towards a diminution rather than an increase in the incidence Moreover, no ill effects analogous to provocation typhoid were produced by the immunisation Even among the 23 contacts found to be carrying paratyphoid bacilli in the stools a few days after the first dose of TAB, only one developed the disease and that in a mild form

Comparison of the incidence of carriers among uninoculated patients and inoculated subclinical cases shows that 3 of the 19 patients who were not inoculated, and 2 of the 23 contacts who received vaccine are still excreting *Bact paratyphosum B* It is therefore clear that while immunisation did not increase the incidence of the carrier condition, it certainly did not prevent it

SUMMARY

An outbreak of paratyphoid fever in a closed community of 80 persons with exceptional opportunities for cross-infection is described

All the contacts were immunised with TAB vaccine and this was followed by routine examination of fæces over several weeks

The number of contacts who excreted *Bact paratyphosum B* in the fæces without developing symptoms exceeded the number of clinical cases and formed a potential reservoir for the spread of infection

Immunisation of patients after exposure to infection appeared to have no harmful effects and may possibly have been a factor in the abrupt termination of the outbreak

The carrier-rate was not appreciably influenced by immunisation

We should like to thank Lord Stamp for his assistance with this work and the nursing staff for their help in collecting the specimens

BILATERAL CONGENITAL SUBLUXATION OF THE ACROMIOCLAVICULAR JOINT

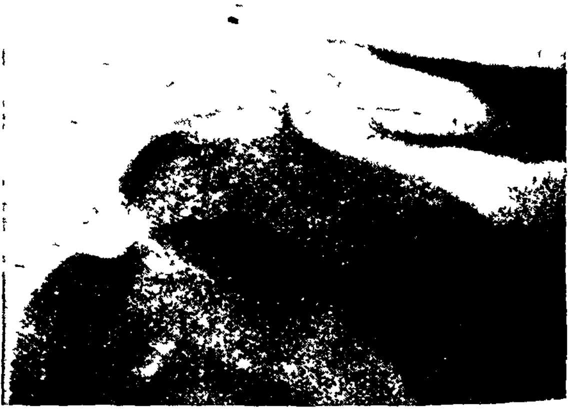
JOHN GRIEVE, M B, B SC ST AND
FLIGHT-LIEUTENANT, RAFVR

CONGENITAL dislocations and subluxations in the region of the shoulder are not common, in fact only one example of congenital dislocation of the acromioclavicular joint appears to have been recorded, and Smith,[1] who reported it in 1870, was unable to find any genuine examples published before that date The following two cases of bilateral congenital subluxation of the acromioclavicular joint were seen at recent air-crew medical examinations

CASE-HISTORIES

CASE 1 —A man of 20 He had been a full-time breast fed baby weighing 8 lb at birth The confinement was uneventful and the presentation vertex He gave no history of serious illness or injury and said he had known for several years that his shoulders were more prominent than those of his fellows, and that he had felt self conscious about them when bathing and swimming He volunteered the information that his father was exactly the same and that he likewise had suffered no injury to his shoulders, unfortunately owing to war conditions it has been impossible to examine the father His mother, brother and two sisters were fit and had no similar deformity No abnormalities were known in preceding generations or in collaterals He was of medium build and average muscular development Casual inspection showed that some abnormal condition was present at the outer end of both clavicles The outer end of each clavicle was 1 5 cm above the acromion and overriding it by 0 5 cm The capsule of the joint was lax and the clavicle could easily be moved in an anteroposterior direction, but less easily laterally Reduction was almost complete but unstable Movement at the shoulder was full and free both with a fixed and mobile scapula It was not practicable to take a radiogram

CASE 2 —A man of 18 He had been a full time normal baby whose delivery was uneventful He had sustained no injuries and said the ends of his collarbones had been prominent for as long as he could remember Apart from an abscess in the region of his left elbow at the age of 6 years he had had no illness of note His father, mother and two sisters were alive and well and no deformities were known in his family or in the collaterals He was well built and of more than average height The lateral ends of both clavicles were much more prominent than usual and were raised 1 cm above the acromion, overriding it by 0 5 cm Reduction was easy but unstable Movements were full and he experienced no disability The left fifth metatarsal was shortened and the small toe poorly developed In all other respects he was apparently normal The bilateral subluxation was confirmed radiographically (see figure)



Radiogram in Case 2

DISCUSSION

The example of congenital dislocation of the acromioclavicular joint reported by Smith was in a macerated specimen of unknown origin in which the outer end of the clavicle was poorly developed, and in which the articular surface of the acromion was missing The evidence for its congenital nature was circumstantial In the cases here reported the evidence is again circumstantial but satisfactory Even after repeated questioning of the first candidate, and in information supplied by his father in a carefully worded questionnaire, no history of antecedent trauma was obtained It is most unlikely that any one could acquire a bilateral subluxation of the acromioclavicular joint without being aware of injury Indeed, with the probability that the father has a similar condition (again without history of trauma) one might go even further and consider the possibility of heredity The second candidate was equally emphatic that he had had no injury

On several occasions, less definite examples of bilateral subluxation have been seen In these the displacement was not more than 0 5 cm, but in each case there was definite evidence of laxness of the capsule of the joint It seems therefore that some degree of laxity of the capsule is not so very rare, and may predispose to poor results in subsequent acquired dislocation or subluxation

Experience has shown that in acquired subluxations and dislocations reduction is not essential for the full return of function, but the first patient showed that psychological ill effects of non-reduction are possible thus he feels that he is not as other men and wonders how important this may be It seems that, in treating subluxation and dislocation of the acromioclavicular joint, the cosmetic result is at least as important as the functional

I wish to thank Dr F H Kemp of the Radcliffe Infirmary, Oxford, for taking radiograms of the second candidate and the librarian of the Royal Society of Medicine for his help in trying to trace further examples

CORROSIVE PYLORIC STENOSIS WITHOUT ŒSOPHAGEAL INVOLVEMENT

D P DEGENHARDT
M B EDIN
ESIDENT MEDICAL OFFICER

RONALD G HENDERSON
M B, B SC GLASG, F R C S E
RESIDENT SURGICAL OFFICER

AN EMS HOSPITAL IN SCOTLAND

WE had the opportunity recently of studying a patient with pyloric stenosis due to corrosion as a result of drinking acid The peculiar feature of the case was that there was no involvement of the œsophagus The article by C A R Schulenberg in the *Lancet* of Sept 27, 1941 p 367), brought the rarity of this condition to our notice. Our patient showed much the same features as the one he described—no involvement of the mouth, throat, or œsophagus either of an acute or chronic nature, and the rapid onset of the stenosis

A man of 36 had always been nervous, shy, and backward in company Since 14 years of age he had been subject to depressive attacks During these attacks he has had amnesic periods In one attack, 4 weeks before admission to this hospital, he attempted suicide by drinking acid out of a battery The only thing he could remember was that he had been violently sick afterwards Ever since then he has had increasing thirst and inability to keep food down On admission here he had the typical symptoms of pyloric stenosis once a day he vomited large quantities of fluid He was somewhat dehydrated The X-ray report was "Œsophagus no evidence of constriction, no delay in passage of bolus of barium cream to stomach Stomach very atonic, attempt at peristalsis After manipulation in supine position a thin stream of barium passed into the duodenum Summary extreme narrowing of the prepyloric area of the stomach with somewhat enlarged and atonic stomach"

After a few days on rectal salines and stomach lavage a posterior gastro-enterostomy was performed by Mr A M Clark Gross thickening of the pyloric region was found, the rest of the stomach appearing normal He made an uneventful recovery

Though the acid swallowed was probably not very weak—the acid in a battery is usually 28% H_2SO_4—it cannot have been long enough in contact with the rest of the alimentary canal to cause injury, but at the pylorus it was held up by spasm and was in contact with the mucosa long enough to cause serious corrosion

We wish to thank Dr W J Richard and Mr A M Clark for permission to publish this case

SPERM SURVIVAL IN RUBBER SHEATHS

JOHN TYNEN, R M RANSON

NOW that the collection in rubber sheaths of the seminal fluid of man and animals is becoming increasingly common, both for pathological investigation and for artificial insemination, the question of sperm survival in rubber sheaths is important The object of this note is to emphasise the fact that the majority of sheaths now obtainable are toxic to human sperms, as measured by the time of survival of the sperms under standard conditions of storage Owing to the war further supplies of the least toxic sheaths previously examined by one of us (R M R *Lancet*, 1937, i, 1400) are no longer available in this country, for they were of Continental manufacture

Experiments have been undertaken with a view to extracting the toxic substance from the sheaths now obtainable Since it seemed obvious, from the rapidity with which sperms were killed by the more toxic sheaths, that the toxic substance was readily soluble in semen, initial attempts to extract this were made with isotonic solutions containing gelatin and egg-white, and having a pH value approximating to that of human semen These solvents were found to be only very slightly superior to hot soap solutions as detoxicants Various other solvents, such as ether, chloroform, &c were tried with indifferent success However, it was found that by soaking the sheaths in hot alkaline solutions of industrial spirit, the toxic action could be greatly reduced

Samples of 17 popular brands of sheath were examined for toxicity both before and after washing with hot soap solutions or alternatively with hot industrial spirit containing ammonia. The mean survival-times of fresh human sperms maintained at 37° C in the unwashed, soap-washed, and spirit-washed sheaths were 50, 86, and 140 minutes When the sperms were stored for 15 minutes in the sheaths and then transferred to glass vessels the mean survival-times were 90, 160, and more than 360 minutes Occasionally, sperms which had been stored for 15 minutes in a spirit-washed sheath and then transferred to a glass tube were found to be still feebly active at the end of 24 hours

If, therefore, it is essential for pathological or clinical purposes to employ a sheath of minimal toxicity to sperms, it should be immersed for about 10 minutes in a mixture of about 200 c cm of industrial spirit and 10 c cm of dilute ammonia solution (*BP*) at about 50° C The sheath should be turned inside out at least once during the treatment, at the end of which it should be rinsed with tap water, dried, and freely dusted with talc The use of starch for dusting is inadvisable owing to the close similarity of the microscopical appearance of the granules to that of concretions occasionally appearing in semen, whence identification of the latter is complicated The patient should be told to transfer the semen from the sheath to a glass tube as soon as possible

It seems likely that the "fillers" and "accelerators" used in the manufacture of rubber sheaths are the source of the toxic action Experiments with saturated saline solutions of mercaptobenzthiazole revealed the high spermicidal power of this substance, which is an example of the type of substance commonly employed in rubber vulcanising processes

The chemical and biological work has been carried out in the Research Laboratories of the British Drug Houses Ltd, to the directors of which we are indebted for permission to publish this memorandum

PERIPHERAL NERVE PALSIES FOLLOWING INTRAMUSCULAR INJECTIONS OF SULPHONAMIDES

J ST C ELKINGTON, MD CAMB, F R C P
PHYSICIAN IN CHARGE, NEUROLOGICAL DEPARTMENT,
ST THOMAS S HOSPITAL

THE object of this communication is to draw attention to the serious damage which may result from the intramuscular injection of sulphonamides in the close neighbourhood of peripheral nerves Three such cases have come under my observation

CASE 1—A healthy young man contracted meningococcal meningitis and was removed to hospital The attack was typical and of moderate severity and he received a full course of sulphapyridine, partly administered by intramuscular injection of the diluted sodium salt into alternate buttocks In all 7 injections were given Seven days later it was observed that he was unable to move his right foot, which together with the lower part of the leg was numb He has no recollection of the first five days after admission to hospital He was discharged from hospital 8 weeks after admission When examined a fortnight later he showed signs of complete loss of function of his right sciatic nerve There was moderate wasting and complete loss of voluntary power in the lower part of the biceps femoris and of all muscles below the knee The ankle jerk was lost and there was complete sensory loss in the distribution of the sciatic nerve in the foot and leg The skin of the foot was dry and atrophic At about the level of the junction of the middle and upper thirds of the thigh (5 in below the great trochanter), a little lateral to the line of the sciatic nerve, one could feel an ovoid mass about 1½ in long and 1 in wide Pressure on this produced neither local discomfort nor referred sensations in the foot There has been no recovery in six months

CASE 2—A previously healthy man was admitted to a hospital on account of an infected blister on the right heel He was critically ill and in addition to local treatment to the foot an intramuscular injection of sodium sulphapyridine was given into the outer aspect of the right arm Two days later it was observed that he had right wrist drop. When examined 6 weeks later he had signs of a complete radial nerve palsy Apart from all three heads of the triceps, all muscles supplied by the radial nerve were wasted and completely without voluntary power There was slight impairment of sensation along the radial border of the forearm and hand. No recovery has occurred in six months

CASE 3—A previously healthy man was wounded in the left arm by a bomb splinter. On reaching this country 2 days later an immediate operation was performed on his arm, which had become heavily infected. As far as can be ascertained from his records, he received injections of sodium sulphapyridine and he says that at least one injection was given into the left buttock The day after the operation on his arm the left leg was found to be powerless below the knee, having been normal in all respects before Nine months later the signs indicated a severe partial lesion of the left sciatic nerve There was complete loss of power with severe wasting in all the muscles of the anterior and lateral compartments of the left leg, with weakness of the flexors of the ankle and toes Sensation was severely impaired on the dorsum of the left foot and the outer aspect of the lower third of the leg, but there was no area of complete loss Electrical examination showed complete reaction of degeneration in the anterior tibial muscles This patient's progress has been followed and the signs have not changed in 15 months

In cases 1 and 2 the physiological interruption of the nerve was complete and in case 3 very severe In no case has any evidence of recovery shown itself at present In cases 1 and 2 the damage can be attributed with almost complete certainty to the drug, which in these cases was sodium sulphapyridine In the third case *it is* not possible to be quite so certain, as the hurried notes made at the time indicate that in addition to sulphapyridine sera were also administered by injection

The practical conclusions to be drawn appear to be (1) that sulphonamides should only be administered by intramuscular injection when the oral route is impracticable, (2) that they should then be administered only by a medical man, (3) that they should be given into muscles as remote as possible from an important peripheral nerve—e g , into the vastus externus, and (4) that the most rigid asepsis should be insisted on, the instruments being boiled rather than sterilised by chemical agents

Cancer of the Uterus

ELIZABETH HURDON, CBE, MD Toronto, first director of the Marie Curie Hospital, London, and late associate in gynecology, Johns Hopkins University London Humphrey Milford, Oxford University Press Pp 187, 17*s* 6*d*

THIS book, published after its author's death, is a record of her unique experience and remarkable clinical judgment , it is besides a standard textbook on cancer of the uterus based on fourteen years' work in a clinic which has produced some of the best results ever obtained in the treatment of this form of cancer A table showing local cures in relation to grade and stage of the disease suggests that the histological grade is of little significance —a point which Dr Hurdon emphasised Clinical observation has shown that the stage of the disease is all-important, and that delay in treatment is a serious mistake In a chapter on general clinical techniques she passes on information obtained by careful observation over many years A special chapter deals with dosage calculation and distribution Prof W V Mayneord, working with her, measured the radiation obtained from the intracavity applicators used at the Marie Curie Hospital Dr Hurdon found it desirable to pack the applicators well up into the lateral fornices , satisfactory dosage depends on getting the radium in good position It is unfortunate that there was not time for another study of the dosage in more advanced cases where ideal arrangement is impossible but where nevertheless some remarkable five-year cures were recorded Remaining chapters cover treatment of complications, results of treatment, and other malignant conditions including sarcoma of the uterus, cancer of the vagina, and cancer of the vulva The section on results is impressive , the five-year survival-rate of 36% of all cases treated sets a standard for other radiotherapists

Reception of William Beaumont's Discovery in Europe

Dr GEORGE ROSEN London Baillière Pp 97 38*s* 6*d*

Dr Rosen feels that few have estimated the interest roused in Europe by Beaumont's work on gastric secretion, and has set himself the task of filling the gap At the time of Beaumont's work an active dispute about the facts was in progress on the Continent, especially in Germany, where accepted hypotheses were being examined afresh Beaumont's work was enthusiastically received there, even before the publication of his book The leading German physiologists quickly realised the importance of the work, and in England the new ideas were welcomed soon afterwards , but curiously little interest was displayed in France for several years With the general acceptance of the newer teaching founded on Beaumont's work his name, as Dr Rosen shows, disappeared from the records, and it was not till the beginning of this century that Beaumont's reputation as an original researcher was revived He was worthy of recognition, as the records of his life and of the extreme accuracy with which he planned and recorded his experiments show Some of his conclusions were mistaken, but the main facts he established have stood the test of time

Immunology

(2nd ed) NOBLE PIERCE SHERWOOD, MD, PhD, FACP London Henry Kimpton Pp 639 33*s*

THE appearance of a second edition six years after the first suggests that this book has had moderate success, although medical students for whom it was intended will find it hard reading The text suffers in places from over-compression, and the relative importance of statements of fact is not always indicated , Professor Sherwood's own conclusions should be more in evidence Paragraph headings have been improved in this edition and are useful for ready reference Advanced workers should benefit from a perusal of chapters dealing with their own specialty, but will be surprised by the inclusion of much obsolete material and by strange omissions , for example, no mention is made of the work of Todd on streptolysin, nor of Burnet, Bigger, Dolman and others on staphylococcus toxin and antitoxin A more critical account is required of diphtheria prophylactics, and Schick-test toxin should have been defined in terms of combining power and not of guineapig MLD Hypersensitiveness and the chemistry of antigens are well summarised The book is attractively produced and is recommended to supplement but not replace other volumes on immunology At the end of each chapter are long and valuable lists of references

Binocular Imbalance

MARGARET DOBSON, MD Lond London H K Lewis Pp 96 10*s* 6*d*

SINCE Claud Worth classified the degrees of binocular vision, from simultaneous macular perception to full stereoscopic vision, increasing attention has been paid to the ocular muscles and their relation to eyestrain As Miss Dobson points out, experience has shown that of all causes of eyestrain that lie with the external ocular muscles, the commonest is convergence weakness Whether man was intended to spend 8 hours a day at close work is a matter for argument, but there is no doubt that doing so calls for a sustained muscular effort which at times taxes him severely Miss Dobson gives an account of the causes of eyestrain other than those due to errors of refraction, and there is much useful information in her book Eye exercises have become the vogue and are expected to cure anything from myopia to cataract This book gives a restrained account of the help that may be gained from them The intimate association between convergence and accommodation is well explained and there are some useful hints for those prescribing glasses for presbyopia Not many oculists will agree that all manifest hypermetropia must necessarily be corrected for distant wear, Miss Dobson has had her defeats over it, seemingly, for she says, " it is frequently difficult to assure patients that this is necessary as slightly blurred vision is so well tolerated " The information conveyed in this book is not always easy to extract and a more concise definition of some of the terms used would have made for easier reading

THE LANCET

LONDON SATURDAY, OCTOBER 10, 1942

RICKETS IN THE BREAST-FED BABY

A MOTHER in the *Nursery World* for Sept. 10 is worried because her baby at the age of 18 months has been admitted to hospital for the treatment of rickets, despite the fact that she suckled him for 9 months and later included halibut oil in his diet. Is it something lacking in war-time diet? she asks, and goes on to suggest that hers is a common problem. If so, practitioners will be asked about prophylaxis. This mother says her son's legs were bandy as soon as he began to walk, but a certain amount of bandiness is a normal phenomenon, and in chubby babies the muscle bellies of the legs give an erroneous idea of the shape of the bones. Careful X-ray examination with soft rays will reveal in many instances perfectly straight bones, although the soft parts look unnaturally curved.[1] So radiological diagnosis is essential to establish the presence of rickets, and orthopædic surgeons are perhaps too ready to ascribe bow legs and knock knees to rickets. The next point concerns breast milk and its vitamin-D content. This must depend largely on the mother's diet and state of health, and breast-feeding by no means excludes the risks of rickets. Indeed, experience in places where rickets was rife indicated that when rickets does arise in the breast-fed it is likely to be severe. But rickets does not seem to have become unduly prevalent since the war began, and in this particular case the mother lived in the country and her diet was said to be generous, containing milk, eggs and vegetables. The mother does not mention her vitaminised margarine, a most valuable source of vitamin D for her and indirectly for the baby (60 IU per oz.), but even with this the findings in Australia mentioned in these columns[2] a few weeks ago suggest that the expectant mother in good hygienic and dietetic circumstances needs extra vitamin D as well as extra calcium if her baby is to be fortified against rickets. The third point is that rickets is a disease of growing bones, and the more rapid the growth the greater the chance of rickets. Thus arises the paradox of the breast-fed baby who is doing exceptionally well on his diet and growing so fast that even a normal ration of vitamin D is not enough for him. In other words, the total amount of vitamin D available in his mother's milk daily is, in relation to his size and growth, relatively deficient. It is just this over-fed, contented fat baby who not only looks bandy when he gets on his legs but because of his rapid growth and over-weight condition may actually develop some bending of his relatively poorly calcified bones. If he had not done so well on the breast he might not have been bandy.[1] *Large* doses of cod-liver oil, at and after the time of weaning, may make matters worse by encouraging too rapid growth. The remedy is twofold. First, see that expectant mothers take vitamin D in adequate amounts and really drink their pint of milk daily during the last three months of pregnancy and that they do not give them up while they are suckling the baby. Secondly see that every breast-fed baby gets some cod-liver oil, or its equivalent, right through the rickety period—up to 2 years. Start with a few drops daily at a few weeks old and work up steadily to 30–45 minims a day at 6 months, when mixed feeding begins. The increase should continue, aiming at 60–90 minims at a year old. Certain modifications in this programme may be permitted. In summer the baby under 6 months can do with less cod-liver oil but after that age the demands for vitamin D are so great that it is risky to reduce the dose much. The over-weight baby needs special care and whenever possible a vitamin concentrate is better than cod-liver oil for him.

THE AMPUTEE'S POINT OF VIEW

THE unshapely artificial limb that a Syme's amputation necessitates has been advanced, especially in the case of a woman, as an argument in favour of the below-knee amputation.[1] WHEELER,[2] having seen excellent and lasting functional results with the Syme amputation, urges that it is up to the instrument maker to fashion a more shapely limb and considers that the average woman would ignore reasons of show for the sake of the more stable, useful stump. A woman who has had first a Syme and then a below-knee amputation done does not agree. Ten years ago, when at the age of 18 she had a Syme for a badly crushed foot, she was at first appreciative of her surgeon's conservatism, but she soon regretted that her stump did not allow a natural looking foot to be fitted; her thick ankle and limited motion at the joint made it obvious that she had an artificial foot. She could walk all day and dance as much as she liked, but she could not dance properly or wear dancing slippers. In a blitz her leg was burnt badly enough to necessitate re-amputation through its middle, and when her below-knee artificial leg was fitted she was delighted to see herself in the glass standing on two normal and evenly shaped legs. Now people no longer realise that she has an artificial leg; she can walk as well as she did with her Syme and dance better in proper shoes; but above all she is no longer labelled a cripple.

Limb-fitting surgeons have given much consideration to the emotional outlook of amputees, and they have been divided into three groups by an American committee, composed of surgeons and limb manufacturers, who have recently issued an admirable handbook on amputations.[3] First, there are those whose amputation is performed for chronic diseases such as bone infection, vascular insufficiency or malignant disease. These accept their loss as a blessing and a welcome escape, and are content with any form of prosthesis, even though it be unshapely or ungainly. In a second group a planned re-amputation is done to enable a more becoming and useful prosthesis to be fitted. The woman whose opinion has been quoted comes in this category. These are the most gratifying patients of all for the surgeon—they look forward to the operation, plan, and are eager to start life afresh. In the last group are those recently mutilated by accident or warfare. Here the healthy patient must suddenly realise that he will have supplied by the radial nerve were wasted and completely without voluntary power There was slight impairment of sensation along the radial border of the forearm and hand. No recovery has occurred in six months

[3] Handbook on amputations. By a joint committee of the American Medical Association and the Association of Limb Manufacturers of America. Chicago: American Medical Association. 1942. Pp. 82.

CASE 3—A previously healthy man was wounded in the left arm by a bomb splinter On reaching this country 2 days later an immediate operation was performed on his arm, which had become heavily infected As far as can be ascertained from his records, he received injections of sodium sulphapyridine and he says that at least one injection was given into the left buttock The day after the operation on his arm the left leg was found to be powerless below the knee, having been normal in all respects before Nine months later the signs indicated a severe partial lesion of the left sciatic nerve There was complete loss of power with severe wasting in all the muscles of the anterior and lateral compartments of the left leg, with weakness of the flexors of the ankle and toes Sensation was severely impaired on the dorsum of the left foot and the outer aspect of the lower third of the leg, but there was no area of complete loss Electrical examination showed complete reaction of degeneration in the anterior tibial muscles This patient's progress has been followed and the signs have not changed in 15 months

In cases 1 and 2 the physiological interruption of the nerve was complete and in case 3 very severe In no case has any evidence of recovery shown itself at present In cases 1 and 2 the damage can be attributed with almost complete certainty to the drug, which in these cases was sodium sulphapyridine In the third case it is not possible to be quite so certain, as the hurried notes made at the time indicate that in addition to sulphapyridine sera were also administered by injection

The practical conclusions to be drawn appear to be (1) that sulphonamides should only be administered by intramuscular injection when the oral route is impracticable, (2) that they should then be administered only by a medical man, (3) that they should be given into muscles as remote as possible from an important peripheral nerve—e g, into the vastus externus, and (4) that the most rigid asepsis should be insisted on, the instruments being boiled rather than sterilised by chemical agents

Reviews of Books

Cancer of the Uterus

ELIZABETH HURDON, CBE, MD Toronto, first director of the Marie Curie Hospital, London, and late associate in gynecology, Johns Hopkins University London Humphrey Milford, Oxford University Press Pp 187 17*s* 6*d*

THIS book, published after its author's death, is a record of her unique experience and remarkable clinical judgment, it is besides a standard textbook on cancer of the uterus based on fourteen years' work in a clinic which has produced some of the best results ever obtained in the treatment of this form of cancer A table showing local cures in relation to grade and stage of the disease suggests that the histological grade is of little significance —a point which Dr Hurdon emphasised Clinical observation has shown that the stage of the disease is all-important, and that delay in treatment is a serious mistake In a chapter on general clinical techniques she passes on information obtained by careful observation over many years A special chapter deals with dosage calculation and distribution Prof W V Mayneord, working with her, measured the radiation obtained from the intracavity applicators used at the Marie Curie Hospital Dr Hurdon found it desirable to pack the applicators well up into the lateral fornices, satisfactory dosage depends on getting the radium in good position It is unfortunate that there was not time for another study of the dosage in more advanced cases where ideal arrangement is impossible but where nevertheless some remarkable five-year cures were recorded Remaining chapters cover treatment of complications, results of treatment, and other malignant conditions including sarcoma of the uterus, cancer of the vagina, and cancer of the vulva The section on results is impressive, the five-year survival-rate of 36% of all cases treated sets a standard for other radiotherapists

Reception of William Beaumont's Discovery in Europe

Dr GEORGE ROSEN London Baillière Pp 97 38*s* 6*d*

Dr Rosen feels that few have estimated the interest roused in Europe by Beaumont's work on gastric secretion, and has set himself the task of filling the gap At the time of Beaumont's work an active dispute about the facts was in progress on the Continent, especially in Germany, where accepted hypotheses were being examined afresh Beaumont's work was enthusiastically received there, even before the publication of his book. The leading German physiologists quickly realised the importance of the work, and in England the new ideas were welcomed soon afterwards, but curiously little interest was displayed in France for several years With the general acceptance of the newer teaching founded on Beaumont's work his name, as Dr Rosen shows, disappeared from the records, and it was not till the beginning of this century that Beaumont's reputation as an original researcher was revived He was worthy of recognition, as the records of his life and of the extreme accuracy with which he planned and recorded his experiments show Some of his conclusions were mistaken, but the main facts he established have stood the test of time

Immunology

(2nd ed) NOBLE PIERCE SHERWOOD, MD, PhD, FACP London Henry Kimpton Pp 639 33*s*

THE appearance of a second edition six years after the first suggests that this book has had moderate success, although medical students for whom it was intended will find it hard reading The text suffers in places from over-compression, and the relative importance of statements of fact is not always indicated, Professor Sherwood's own conclusions should be more in evidence Paragraph headings have been improved in this edition and are useful for ready reference Advanced workers should benefit from a perusal of chapters dealing with their own specialty, but will be surprised by the inclusion of much obsolete material and by strange omissions, for example, no mention is made of the work of Todd on streptolysin, nor of Burnet, Bigger, Dolman and others on staphylococcus toxin and antitoxin A more critical account is required of diphtheria prophylactics, and Schick-test toxin should have been defined in terms of combining power and not of guineapig MLD Hypersensitiveness and the chemistry of antigens are well summarised The book is attractively produced and is recommended to supplement but not replace other volumes on immunology At the end of each chapter are long and valuable lists of references

Binocular Imbalance

MARGARET DOBSON, MD Lond London H K Lewis Pp 96 10*s* 6*d*

SINCE Claud Worth classified the degrees of binocular vision, from simultaneous macular perception to full stereoscopic vision, increasing attention has been paid to the ocular muscles and their relation to eyestrain As Miss Dobson points out, experience has shown that of all causes of eyestrain that lie with the external ocular muscles, the commonest is convergence weakness Whether man was intended to spend 8 hours a day at close work is a matter for argument, but there is no doubt that doing so calls for a sustained muscular effort which at times taxes him severely Miss Dobson gives an account of the causes of eyestrain other than those due to errors of refraction, and there is much useful information in her book Eye exercises have become the vogue and are expected to cure anything from myopia to cataract This book gives a restrained account of the help that may be gained from them The intimate association between convergence and accommodation is well explained and there are some useful hints for those prescribing glasses for presbyopia Not many oculists will agree that all manifest hypermetropia must necessarily be corrected for distant wear, Miss Dobson has had her defeats over it, seemingly, for she says, "it is frequently difficult to assure patients that this is necessary as slightly blurred vision is so well tolerated" The information conveyed in this book is not always easy to extract and a more concise definition some of the terms used would have made for is the method whereby maximum oxygenation of the heart and brain is maintained. The blood entering the heart through what BARCLAY and his colleagues describe as the inferior-posterior caval channel flows mainly through the foramen ovale to the left side of the heart and thence enters the first part of the aorta, thus supplying the heart and the brain. The blood entering the heart through the superior-anterior caval channel passes in its entirety to the right side of the heart and is thence distributed (together with the smaller fraction of the inferior-posterior caval flow, and the coronary venous return) in part to the pulmonary arteries and in part via the ductus arteriosus, to the descending portion of the aorta—i.e., it enters this vessel distal to the offshoots supplying the heart and the brain respectively. The advantage of this arrange- is obvious; the more highly oxygenated blood from the placenta goes direct to the heart and the brain, while the rest of the fœtal organism, whose demands for oxygen are much less stringent, is supplied principally by blood which has already made a cardiac or cerebral circuit. The two outstanding problems of the closure of the ductus arteriosus and of the foramen ovale have also been clarified. Both are closed within a few minutes of birth, the latter probably closing first; the right group of pulmonary vein entries shares with the foramen ovale an opening into the left atrium, so the inflow through the former can increase only at the expense of the inflow through the latter. The functional closure of the foramen ovale may, therefore, be related to increase in the pulmonary venous return. In the newborn lamb, delivered by cæsarean section, the ductus arteriosus remains patent so long as the placental circulation is effectively maintained. When, however, the umbilical cord is tied there is a complete change, for within a few minutes the ductus is functionally closed, and in a healthy subject it does not thereafter reopen. The time relations of the closure are, therefore, those of a sphincter and not those of cicatrisation. The rapid physiological closure is followed by the very gradual conversion of the muscular sphincter into connective tissue.

The problem of the first breath has been at least partially solved. The essential neuromuscular mechanism for this act is already laid down, in the sheep, between the 34th and 50th day of gestation. From this early stage, when the respiratory movement is the result of a reflex arc consisting of the maxillary branch of the trigeminal nerve, cells in the reticulospinal tract, and the spinal accessory and upper cervical ventral nerve-roots, there is a gradual transition as the higher centres develop and inhibit the lower centres. At birth two main factors come into play—partial asphyxia due to suspension of the placental circulation, and multiple stimuli from the skin due to the removal of the fœtus from its non-stimulating environment of amniotic fluid to the external world. These two factors are undoubtedly the major ones, though whether oxygen want or excess of carbon dioxide predominates is still undetermined. Such, in brief, is the story up to date. Some of it was known before; much of it was suspected, but it is only now that proof has been provided. The progress made in such a short period as 5 years justifies the hope that we may at last really understand the physiology of birth, and secure a foundation for the proper handling of the beginnings of life. This is in its nature essential work

WOUNDS AND FLAVINES

THE war has naturally brought a great revival of interest in the local treatment of wounds. The work has been divided into three main parts—the prevention of hospital infection, the application of prophylactics, and the treatment of established infection. Apart from the widespread use of the sulphonamides as local applications, both in prevention and in treatment, interest has been revived in the hypochlorites by BUNYAN,[1] and in the group of acridine dyes exemplified by acriflavine and proflavine. These dyes have had many protagonists and many antagonists. For example, FLEMING,[2] marshals the evidence against acriflavine, pointing out that 80% of the dye is absorbed from a 1 in 1000 solution by dressing gauze, and that it has a powerful inhibitory effect on the bactericidal power of blood at a concentration of 1 in 270,000 if allowed to act on the blood for four hours before the test inoculum of bacteria is added. JACOBY, MEDAWAR and WILLMER[3] found that proflavine was intensely toxic to fibroblasts in tissue culture, causing an irreversible inhibition of mitosis at concentrations of less than 1 part per million, and might thus be expected to interfere seriously with healing. GARROD[4] however expressed the view that the undeserved contempt for antiseptics which is now so common is largely based on beliefs which arose during the last war, when the almost universal judgment on experiences with casualties in France was that antiseptics had failed, and he considers that because of its constancy of composition, minimal toxicity and relative cheapness, proflavine is the antiseptic of choice.

Proflavine is 2:8-diaminoacridine sulphate and it has some promising relatives. In 1934 ALBERT[5] began the synthesis of a series of acridine compounds, and his work led to the discovery of 2:7-diaminoacridine, which is as powerful an antiseptic as proflavine and acriflavine, yet has only a tenth of the toxicity of acriflavine for mice.[6] Unfortunately, 2:7-diaminoacridine is difficult to make in quantity and has not been generally available, but ALBERT[7] is said to have overcome that difficulty. RUSSELL and FALCONER[8] investigated the histological effects of acridine compounds, coal tar derivatives, halogen compounds, organic mercurials and 'Soluseptasine' on rabbit brain. They found that acriflavine, like most other antiseptics, caused hæmorrhage and necrosis, but that proflavine was little more harmful than isotonic saline solution, with 2:7-diaminoacridine hydrochloride not significantly different, so they recommended the use of proflavine sulphate as a 0.1% solution in isotonic saline buffered to pH 6.3. MANIFOLD[7,9] investigated the effect of a similar series of antiseptics on the respiration of brain tissue, and found that acriflavine was highly toxic, even at very low concentrations, while proflavine was much less toxic, and 2:7-diaminoacridine hydrochloride significantly less toxic than to go through life maimed and must re-shape his future accordingly, often there is the suppressed horror of possible disfigurement. Ultimate adjustment will depend partly on the patient's natural emotional stability, partly on the mental atmosphere of his convalescence The busy surgeon may forget that the stump is but part of the whole. The nursing staff display the sympathy which every amputation evokes, but as the American committee point out such sympathy must not be misplaced, and any tendency to molly-coddling must be curbed. It is important at an early stage for the patient to regain the ambition to embark on his new life Stories of what others have thought and achieved under similar circumstances will encourage and stimulate him Six years ago a man who at the age of 34 had reached the forefront of chest surgery pricked his finger in the theatre, infected it later when doing a dressing and had to have an amputation high up through the arm As he woke from the anæsthetic his first words to his wife were, "Now we shall just have to start all over from the beginning again" H P **Nelson** died soon afterwards but his is an outlook on life which many a man will be wise to adopt.

At Roehampton, by teaching and precept, they make the patient realise that he is not to be dependent on others and must not regard himself as a cripple If others are not so to regard him he must both walk normally and look normal, that is why the Roehampton surgeons urge that, although they can fashion a limb to fit any type of stump, amputations must be done at the sites they suggest It is odd that amputees are so often anxious about the look of the lower limb prosthesis, and yet the arm amputee discards it at the first opportunity, prefers to walk about without an apparatus, and rarely attempts to conceal the disfigurement The Roehampton authorities say that the upper limb should be fitted at the earliest possible moment—usually six weeks—or the patient will learn to do without it For the child too they have laid stress on the importance of early fitting, otherwise as he plays with other children he regards himself as different—a cripple Lower limbs for the child are now so made that they can be easily lengthened, and the child will become particularly adept and proficient with an artificial leg or arm, providing it is early accustomed to its use[4] If the stump is not used till adult life it "loses its place" in the brain Early use of the stump is as important for the adult, and progress will only come if the amputee is keen and anxious to get back to a job The patient has to work if he is to learn to balance, to swing, to walk and to look normal **Jean Camus** wrote in the last war · "Physiotherapy cannot be prescribed as quinine is prescribed The malarial patient who takes the latter medicine benefits whether he wishes to or not The wounded man who submits each morning to his mechanotherapeutic treatment does not recover unless he wishes." We can foster that wish, and A. T. **Lyall**, writing in the *Spectator* (Sept 25), points the way Industry must take a hand, he says, and every employer must consider it his duty, not charity, to train and to place the disabled Man succeeds best when he does the work his heart desires most To train the disabled miner to be a cobbler or a basket-worker is to batten down his spirit to succeed The maimed agricultural labourer must be returned, if at all possible, to his first love, the welder to his trade, the clerk to his desk, and those that would be doctors it should be our function to encourage and support during their training The employer will be well rewarded if it is "with savage determination" that the cripple strives to keep apace—even ahead—of his fellow men

MAMMALIAN BIRTH

One of the curious gaps in our knowledge is that concerning the phenomenon of birth The mechanical aspects are the essence of obstetrics, just as the anatomical development of the fœtus is the essence of embryology But the how and wherefore are only now coming to be understood as a result of the pioneer work of **Barcroft** and his colleagues at Cambridge[1] and of **Barclay** and his colleagues at Oxford[2] As a result of the close cooperation of these physiologists and radiologists it has not only been possible for the first time to observe the circulation in the intact foetus by means of X-ray cinematography, but to understand at least some of the processes which come into play during mammalian birth All these observation have been made on the sheep, but their application to man should be comparatively easy

In the sheep, whose period of gestation is 147 days, the placenta reaches its maximum weight at the 100th day, despite the fact that the fœtus is then only one-eighth of its size at full term Although the volume of the fœtal capillary bed in the placenta remains constant during the last third of pregnancy, adequate oxygenation of the fœtus is maintained by its rising arterial pressure from the 100th to the 130th day and by an increase in the hæmoglobin during the last fortnight So far as oxygen supply is concerned, as **Barcroft** neatly puts it, the fœtus at the 80th day is living at the level of Mont Blanc, by the 130th day it has passed the Andean level, at birth it is under Mount Everest conditions The fœtus as it grows to maturity suffers like the mountaineer from an increasing degree of oxygen want, unlike the mountaineer it cannot meet that situation by panting How far it can be said to acclimatise is not known At birth the blood in the placenta is transferred to the fœtus by contraction of the umbilical and placental vessels, and possibly in man by contraction of the uterus, this overloading of the fœtal circulation is not to supply the newly functioning lungs, which are indeed already vascularised, but to provide a store of iron to see the infant organism through the first few months of life when its intake is inadequate The extra corpuscles are soon broken down and their iron is stored in the liver The closure of the umbilical vessels when the cord is ruptured seems to be brought about by their own contractility, particularly at the level of the umbilicus itself

The circulation and the cardiovascular system in the mature fœtus are much the same as at the 100th day, the main difference being a well-marked fall in the relative weight of the liver which declines from 11% of the body-weight at 69 days to less than 3% at 140 days A remarkable feature of the fœtal circulation the trade union organisation, to supervise and improve safety devices, by way of supplementing the work of the factory inspectors, who are nowadays kept very busy The sections of the pamphlet dealing with eye injuries, hours of work, weight lifting and compensation for injuries are all instructive The compensation section could usefully be issued as a leaflet to each worker, for cases still arise in which an injured man gets no compensation because no one has told him how to apply for it The Factories (Medical and Welfare Services) Order is felt to be only a first step towards an efficient medical service, and the pamphlet objects that the doctor appointed is chosen entirely by the management and that there is no Government supervision of the way he does his work The Ministry of Labour, however, has published a memorandum on the duties to be expected of a factory doctor, which we reviewed last week (p 405) The Industrial Welfare Society has lately revised its booklet[2] on health services in industry, unlike the LRD pamphlet it is addressed mainly to employers The society asks how many panel doctors have been inside a factory or know the conditions in which their patients spend much of their lives There are, in fact, probably about 1700 general practitioners acting as factory surgeons, as well as some 500 odd who have lately been appointed as part time medical officers to factories The doctor best fitted to treat the patient is the one who knows his environment both at home and in the factory General practitioners might well be appointed freely as part time officers to one or more smaller factories, and small firms might combine for the purpose

A REGIONAL ADVISORY COUNCIL GETS TO WORK

In theory regionalisation is much favoured by the planners of today In practice it seems to have made a good beginning on Tyneside The North Eastern Regional Hospital Advisory Council, which meets under the chairmanship of Lord Eustace Percy, is self styled a "purely advisory and consultative body," but its first annual report shows that not only has it established the machinery for future discussions, but it has set those responsible for the health services of the region some searching questions, and seems to be in a fair way to getting the answers Indeed, clouds of careful questionnaires are being broadcast For instance, by arrangement with the MRC and the Nuffield trustees, Dr A Q Wells, reader in pathology in the University of Oxford, has spent several weeks in the region and on the basis of his own observations and on questionnaires completed by the local people concerned he has submitted a report on the pathological services to the council Questionnaires on the hospital facilities available have also been set to the local authorities and to the voluntary hospitals, while the accident service subcommittee have yet another questionnaire now ready for circulation on the fracture services of the region Another side of the council's work is shown by the help it was able to arrange for the Durham County Hospital which during the last years has been faced with a growing burden of debt The hospital applied to the council for help and advice and after investigation the council recommended that the Nuffield Trust should make it a grant on condition that a contributory scheme was at once begun The satisfactory result is that the trustees have agreed to give the hospital £5000 over the next three years and the new contributory scheme already has a membership of over 20,000 and an income of about £10,000 The council is an expression of the common responsibility of the local authorities and the voluntary hospitals to provide hospital services for the people, and it seems to have made a flying start in promoting coöperation, preventing duplication and putting its finger on deficiencies

EXPERIMENTAL LIGHT ON CRUSH SYNDROME

The investigation of trauma in man is made difficult not only by circumstances of time, place and enemy action but also by the multiplicity of insults Thus fright, exposure, hæmorrhage, soft tissue damage and fractures often occur together in the one patient, as well sometimes as the rarer type of injuries such as blast The special advantage of animal experiment over clinical observation is that a single factor may be isolated and studied In contrast to many producers of what is loosely known as "experimental shock," Duncan and Blalock[1] in two recent papers have confined themselves to one main factor—soft tissue damage—in an attempt to reproduce in dogs the analogue of crushing injury in man The limb was clamped between wooden boards at a pressure of 500 lb for five hours under 'Pentothal Sodium' anæsthesia, after release, all but one animal died from "shock," due, as in man, to loss of plasma from the blood stream into the injured area This mortality could be greatly reduced by enclosing the limb immediately after release in a rubber cuff inflated to a pressure of 40 mm Hg A similar but slightly smaller reduction in mortality due to shock was produced both by transfusion of plasma and by keeping the limb at a low temperature during crushing It may be noted that only 33 ml of plasma per kg body-weight was given over a total period of two hours In man, more than this is often required, and over a longer time, if death from shock is to be averted In human crush injury the cause of death is usually, therefore, renal failure, and it occurs not on the first but on the sixth or seventh day In those of Blalock's dogs surviving the shock period, fatal renal failure unfortunately did not appear Oliguria, gross hæmaturia and casts were seen, together with some azotæmia Urinary creatine and creatinine but no urea figures are given, hence we can only assume that this azotæmia was due to nitrogen retention Nor is it possible to compare the effects of therapeutic compression with those of plasma transfusion on the blood non-protein figures, as these are not given for the former group Thus the comparative effects of compression and transfusion on the development of renal damage still remain to be evaluated

Since the human condition is superficially similar to that of mismatched transfusion kidney, in which alkalinisation of the urine is thought to be entirely preventive of renal failure,[2] this seems the treatment to be first tried That has not yet been adequately done, the alkali had been given in too small a dose to change the urinary reaction or too late to affect the result, or the case has been so mild that recovery could already have been forecast More experimental work, on the renal aspect particularly, is badly needed Meanwhile Patey and Robertson[3] maintain that the crush syndrome arises from loss of blood constituents into the injured limb, while the isolation of myohæmoglobin from the urine of five of these patients by Bywaters and others[4] seems to point to substances proceeding from the injured limb being important in the genesis of renal failure On the first of these views Patey and Robertson[5] suggest that the crushed limb should be treated by intermittent positive pressure and tight bandaging to *promote* the absorption of œdema fluid and prevent its formation, while on the second view Curphey[6] advocates tight bandaging or tourniquet to *prevent* the absorption of œdema fluid and of the hypothetical kidney-toxin it picks up from damaged muscle As Duncan and Blalock remark, "further studies are indicated," and they are needed in man as well as in animals

proflavine Acriflavine was always preferred by dispensers, who found it easier to dissolve than proflavine, but as normally prepared acriflavine consists of a mixture of the hydrochlorides of 2 8-diaminoacridine and 2 8 diaminomethylacridinium and may vary considerably in different samples, while proflavine is as good an antiseptic, many times less toxic, and of constant chemical composition

On another page MITCHELL and BUTTLE, working with the Middle East Force, describe the results of applying proflavine as a powder to infected wounds in amounts ranging from 0 25 g to 2 0 g , but usually of 0·5 g or less, never more than three times, at intervals of 4–28 days In their series of 80 cases the powder was often strikingly successful when other methods had failed Neither toxic manifestations nor delayed healing were seen, and they say that where staphylococci are the *infecting organisms*, proflavine powder has proved more efficient in controlling or eliminating infection than any other drug so far tried Probably the drug is here being effectively used for the first time The introduction of the powder directly into the wound seems to be more logical than the time-honoured method of laying on, or lightly packing in a piece of gauze wrung out in a 1 in 1000 watery or oily solution, of which over 80% will be retained by the gauze Proflavine is soluble to 0 3% in saline,[6] and presumably this concentration is approached in the superficial layer of the wound, while 2 7 diamino-acridine hydrochloride is soluble to 0 4%, and appears to be even more promising Many of the other members of this series of compounds, though soluble in water, are precipitated in physiological saline, so despite their interesting properties they are not suitable for use in vivo

Annotations

DRAGON'S TEETH

AN hour or two before his death at the beginning of 1941 Varrier-Jones wrote to Sir Walter Langdon-Brown describing a scheme that had taken hold of him to have a course of lectures at Papworth on the diagnosis and treatment of tuberculosis The scheme, with change of venue but not of purpose, has materialised as his memorial, and on Sept 25 Langdon-Brown paid just tribute to the man and the idea before Wing-Commander Trail delivered the first Varrier-Jones lecture at Halton (see p 413) He retold the story of how Papworth settlement, which today has 500 acres of land, 100 cottages and factories with annual sales running into six figures, grew from one patient put as an experiment in the charge of a capable nurse in the village of Bourn Varrier-Jones, with his peculiar blending of medicine, economics, and sociology had, he said, changed occupational therapy into therapeutic occupation, and today when tuberculosis is once again increasing its inroads we should do well to reflect on this vision—which, as Trail later pointed out, Varrier-Jones had known how to reduce to theory and establish in practice Pendragon was the apt name given to Varrier-Jones by his contemporaries , his followers are harvesting not mutually destructive giants, but revivified citizens

HEALTH OF THE WAR WORKER

THE efficiency of war workers depends on their physical and mental health as well as that imponderable quality called morale The workers themselves are taking an interest in the factors in their environment which affect their health and efficiency, and a pamphlet[1] for their information, published by the Labour industrial health committee, is timely Prepared with the help of the Socialist Medical Association this deals with factory hygiene, food, clothing and transport, accidents, hours of work and factory medical services , the last section suggests how workers themselves can help to tackle health problems in factories If they are exhorted rather more freely to " insist " on safeguards and " demand " information than the conscientious employer would think necessary, it must be borne in mind that not all employers are conscientious , and that men and women still can and do lose life or health from carelessness on the part of the management, as reports of prosecutions show Thus workers are advised to insist on a full report, either from employers or from the factory inspector, on fumes and dust in their working atmosphere Spacing of workers is well discussed and they are told that a barrier of glass or mica between those working face to face *at a distance of a foot or two* will help to prevent the spread of colds or influenza and thus the loss of many weeks of work The pamphlet notes that lavatories in factories are often ill-lit, rarely painted and *have defective flushes or cracked pans* Hand basins, soap and towels may not be conveniently placed for washing after the use of the closet In such cases workers are advised to ask the management for better equipment, and also to make sure that they themselves conform to the standards they would require in their own homes They are reminded of the great importance of washing facilities, since much industrial disease can be avoided if the skin is kept clean They are advised, too, about detergents, and warned that turpentine, benzene and other strong cleansing agents may themselves cause dermatitis Under the Factory Act women who work standing are entitled to a seat for use when opportunity offers This may come as a surprise, the pamphlet suggests, to many of them, and adds with realism that in scores of factories " this section is just a bad joke and is bound to remain so " , but the principle of periodic rests is sensibly explained, and workers are reminded that the clever worker, like the clever footballer, saves himself when he can Output goes up when everyone is made to have a rest pause The comfortable height for a work bench was estimated by the Industrial Fatigue Research Board in 1927, and the figures are given again here—38 in for a man and 37 in for a woman, It seems astonishing that this, too, should not be common knowledge or even common practice The section of the act requiring the management to provide a separate room in which employees working with lead, arsenic or other poisonous substances can take their meals is difficult to enforce because workers themselves are apt to be casual about the danger , for the same reason it is sometimes difficult to get them to make use of protective clothing The pamphlet puts the case for proper precautions clearly and wisely, and suggests that employers should be made to provide protective clothing outside the list of trades where it is now compulsory For example, it seems that many of the 15,000 serious accidents to toes of workers yearly could be avoided if boots with reinforced toe caps were provided for those handling weights Transport difficulties are still hindering production and adding to the fatigue of those already working long hours, and trade unions are advised to take their complaints to the regional production boards Many accidents could be avoided by proper training of new workers , any firm under the Essential Work Order can be required by the Ministry of Labour to provide an adequate training scheme for new entrants, and workers are advised to see that this is done They are also encouraged to form safety committees, run by

[1] Health of the War Worker London Labour Research Department, 6, High Holborn, W C 1 1942 Pp 40 6d

They describe four cases with a history of only a few hours' pain before admission Removal of a normal appendix was followed by radiographic examination which showed ulceration in the first part of the duodenum All cases showed a slightly raised temperature and pulse-rate, tenderness in three cases in the right iliac fossa and abdominal rigidity in two cases Medical treatment was instituted but did not succeed in securing disappearance of the X-ray signs A W Franklin, reporting two cases of duodenal ulceration in childhood, deals with still other clinical features His first case in an infant past the neonatal period exhibited the features of a normal, healthy baby who made a good start with feeding and weight gain and then, after an upper respiratory infection, became "unhappy, refused feeds, slept badly, cried much and became difficult to handle" Changes in food produced transient improvement but a general downhill course led to a fatal ending and the finding of a duodenal ulcer at autopsy with an eroded vessel in its base. In Franklin's other case, a boy of nine years, not only was a duodenal ulcer discovered radiographically and healing secured by medical treatment but there appeared to be a definite psychological factor present in the nature of an anxiety state, which the psychologist predicted "would play a strong part in producing a recrudescence of the symptoms at a future date" Clearly peptic ulceration in infancy and childhood is uncommon but because of its rarity it may be overlooked The clinical pictures emerging from these papers should make diagnosis easier The possible evolution of the child with peptic ulcer into the adult with the same complaint invites speculation

AMERICA'S MEDICAL POOL

LAST year in the medical schools of the United States 20,867 men students were in training, of whom 4884 graduated, and 1164 women students, of whom 279 graduated.[1] This year there are expected to be 22,674 students, but in response to the needs of war-time they will graduate in three years instead of four, these students will already have spent three or even four years at college before entering a medical school All except four of America's sixty-odd medical schools have accepted this principle of acceleration of the curriculum, but there is local option as to how it is to be carried out Most of the schools, however, have chosen the method of accepting a new entry of students every nine months instead of only once a year, and by allowing students to graduate every nine months instead of annually This means cutting out the long vacation, which has created a real problem for many hard-up students who hope to earn enough in the holidays to pay their college fees But the Kellogg foundation has generously come to their help with a grant of 10,000 dollars to each medical school, from which loans will be made Congress has also voted 5 million dollars for loans to students Another problem raised by the speed-up is that in seven states the laws will have to be altered before these accelerated graduates are eligible for licences to practise Hospitals will also have to consider how their system of interneships, which last a year, can be modified to cope with the nine monthly influx of new graduates. It is unlikely that the period of interneship will be shortened but it is suggested that, to begin with, the juniors may be posted to affiliated hospitals. The standards of medical education will not be lowered to meet the new timetable but the curriculum has been reconsidered to see where minor adjustments and better coördination can save time Otherwise the only alteration has been the addition of such topical subjects as military medicine, first-aid, treatment of war wounds, tropical medicine and industrial medicine The staffs of the medical schools have shouldered a heavy war-time burden, for besides the speed up they have agreed to a 10% increase in the numbers of entry classes, and many of the younger teachers have been called up Forty schools have organised affiliated hospital units which will provide the army with staffs, accustomed to working together, who are ready to assume the medical responsibilities of a service hospital These units are of three types general hospitals, evacuation hospitals, and surgical hospitals It is estimated that the next three years should provide over 21,000 new doctors, 5000 more than in normal times The wastage of students, for which due allowance has been made, is based on figures for 1937–41—i e, 16% in the first year, 5% in the second, and 1% in the third By these new arrangements the authorities hope to add two new doctors to the American Medical Directory for every one that will disappear from its pages

LORD NUFFIELD—RCS MEDALLIST

ON the front of the honorary medal which Lord Nuffield received at the President's hands on Sept 30 is the motto of the Royal College of Surgeons and on the reverse is a picture of Galen contemplating a human skeleton Sir Alfred Webb Johnson brought out this wider conception of the college's function when he spoke first of the advancement of surgery for the benefit of mankind and then of the preservation of the broad basis on which the whole edifice of biological knowledge is built Among the 18 previous recipients of the medal are surgeons such as Paget, Lister and Makins, but also men like Richard Owen and Elliot Smith and J A Murray whose claim on the gratitude of posterity is even wider, the second medallist resigned his surgeoncy at a county hospital to take a house in Tavistock Square, where in the billiard room he dissected birds, beasts and fishes, to the lasting benefit of his kind The scope of the medal was already wide enough to include a recipient whose liberal acts have conduced to the advancement of the healing art There is scarce a Dominion, as Mr Gordon-Taylor put it, that has not felt the generous warmth of his outstretched hand, particularly in the care of the maimed, the damaged or the scarred Lord Nuffield admitted it had been his youthful ambition to be a surgeon, instead he had become what Gordon-Taylor called the present-day Vulcan, the blacksmith's god, skilled in metals, the artificer of wondrous things We have already had examples of how his engineering craftsmanship has shortened, or indeed wiped out, the usual lag between scientific conception and delivery of some of the urgent implements of medicine The Minister of Health, who was present at the moving ceremony, expressed his satisfaction that Lord Nuffield had not lavished money on expensive buildings, but had been concerned with the men and women who were to work in them For himself he would praise him for the chairs of social medicine and child health

QUEEN ELIZABETH HOSPITAL FOR CHILDREN

THE first meeting last Friday of the managing board of this amalgamated hospital was followed by an austere but festive luncheon attended by the Primate and the Home Secretary The story of the North-Eastern (just 75 years old) and the East London is like a Grimm's fairy tale in which there was no doubt from the beginning that the two were destined to meet and live together happily ever afterwards Both started like human babes without material possessions but with large heads and rapid hearts Of such is the voluntary hospital tradition and Sir Ernest Pooley, speaking for King Edward's Hospital Fund, expressed the hope of all concerned that, while the State might control and plan, the individual management would be left

EPSOM COLLEGE —A Christie pension of £89 p a will be awarded in November to a necessitous medical man, fully 55 years of age, who has been registered for five years Forms of application may be had from the secretary's office, Epsom College, Surrey, and must be completed and returned by Oct 26

SPINAL ANÆSTHESIA FOR CÆSAREAN SECTION

THOSE who object to the use of a spinal anæsthetic for cæsarean section say that there is a twofold danger for the mother—the risks of a sudden drop in blood-pressure and of a violent reaction to the anæsthetic because the pregnant woman is unduly sensitive to the drug The first can be prevented by the proper use of ephedrine, and this procedure seems unobjectionable in these unshocked patients, there was no example of the second complication in a series lately reported by R C Thomas[1] In 121 cæsarean sections done under spinal anæsthesia one mother died nine days after operation from pulmonary embolism, and in the 123 children born there was one stillbirth and 4 deaths from various causes All his patients were given ephedrine, gr $\frac{3}{4}$, and atropine, gr $\frac{1}{100}$, forty-five minutes before operation Sedative drugs such as morphine and hyoscine were avoided, and the babies were therefore born without *respiratory depression If necessary*, ephedrine was repeated during operation Thomas does not use spinal anæsthesia for any woman with a systolic pressure of less than 105 mm Hg, these he treats by transfusion and if the pressure cannot be raised to an appropriate level he gives them gas, oxygen and ether Since many patients requiring cæsarean section have placenta prævia and are liable to hæmorrhage, they are moved with great gentleness and a supply of blood is at hand in case emergency transfusion should be required In all but 3 cases in his series the drug used for spinal anæsthesia was heavy 'Nupercaine,' but the exact dosage is not stated The mothers remained calm and cheerful throughout, and this was particularly noticeable in 5 women operated on during air-raids Apart from the 121 cases mentioned there were 8 others to which a spinal was given and in which anæsthesia was not sufficient for surgical requirements They were given supplementary anæsthesia and were therefore not included in the series In the absence of fuller details it is impossible to say *whether the drug or the technique was to blame for these* failures The advantages of spinal over general anæsthesia were well shown there was good relaxation of abdominal muscles, a well contracting uterus and no respiratory depression in the babies Infants reluctant to breathe were given an injection of lobeline into the umbilical cord, none of the infant deaths could be attributed to the anæsthetic

COMPLEMENT FIXATION IN TYPHUS FEVER GROUP

THOUGH the Weil-Felix reaction with *Proteus OX19* may indicate the presence of a rickettsial disease, it does not differentiate between typhus and Rocky Mountain spotted fever Since the clinical differentiation between these diseases is very difficult the only means of diagnosis in the past has been the inoculation of guineapigs with blood from the patient immediately it has been withdrawn Many unsuccessful attempts at complement fixation have been made with various antigens such as alcoholic extracts of organs of fatal cases, extracts of infected lice, infected guineapig tissues and infected tick eggs Probably all were unsatisfactory because an insufficient number of rickettsias were present In 1936 Castaneda[2] obtained positive complement fixation in cases of active and past infection with Mexican typhus and Brill's disease, using rickettsia from X-rayed rats infected with endemic typhus A prolific source of typhus rickettsias was made available by Cox's discovery[3] of their ready cultivation in the yolk sac of the developing chick embryo Bengston[4] has used as an antigen rickettsia grown by this method in a specific complement-fixation reaction for "Q" fever and endemic typhus Bengston and Topping[5] have more recently demonstrated that the test will clearly differentiate between endemic typhus and Rocky Mountain spotted fever Using an antigen prepared from endemic typhus, they *found that in a case of laboratory infection* the complement-fixation reaction was positive to a titre of 1/8 on the 10th day, rising to 1/4096 on the 15th day, and then dropping slowly to 1/512 on the 180th day The Weil-Felix reaction was positive in a dilution of 1/80 on the 6th day and 1/320 on the 9th day, but fell more rapidly In 53 cases of past infection the titre was 1/16 or higher even as long as 5½ years later In contrast, 18 specimens from 14 cases of active Rocky Mountain spotted fever were all completely negative Now Plotz and Wertman[6] have confirmed the usefulness of the test by using an antigen of Rocky Mountain spotted fever rickettsia grown in tissue cultures, using the semi solid agar method in Kolle flasks Sera from 9 cases of Rocky Mountain spotted fever all gave positive complement fixation The earliest positive serum was obtained on the 12th day of illness with a titre of 1/24, and the serum of the oldest case who had had the disease 4½ years previously was positive in a dilution of 1/12 All sera from patients who had had Brill's disease or various other illnesses were completely negative A corresponding result was obtained with sera from infected guinea pigs Though more or less specific for the typhus group of fevers, the Weil-Felix reaction being an indirect test has never been happily accepted by many workers These new antigens may give us a simple inexpensive direct test for diagnosing this group of diseases It will be interesting to learn if the complement fixing antibodies are related to the neutralising antibodies If the two antibodies are comparable this will offer a simple means of testing the efficacy in humans of the various anti-typhus vaccines in use

PEPTIC ULCER IN CHILDHOOD

THE early onset of some peptic ulcers has been confirmed in the course of mass investigations of young soldiers with dyspepsia, according to Tidy and others,[7] and now three papers have appeared on peptic ulcer in childhood[8] K J. Guthrie describes nine cases, all coming to autopsy at the Glasgow Royal Hospital for Sick Children in the period 1914–41 All but one were in infants under six months of age and the ulcers seem to have originated after birth Sexes were equally affected and eight of the ulcers found were duodenal, one being gastroduodenal Guthrie draws attention to the peculiar circumstances in the newborn period which predispose to ulceration Circulatory instability, asphyxia and umbilical sepsis may play a part, and any damaged area becomes liable to digestion by the gastric juice, which according to recent work reaches a high degree of acidity in the first forty-eight hours of life Another possible factor is irritation of the mucosa by unsuitable feeding or drugs, of which castor oil is the most blame*worthy and is still too often used by midwives* In the Glasgow series the ulcers were small, never exceeding 1 cm in diameter and almost exclusively lying in the posterior wall of the duodenum above the ampulla of Vater Clinically, hæmorrhage from the stomach or bowel seemed to be the most characteristic sign of peptic ulcer in infants It might be the initial feature, it might be preceded by symptoms of indigestion, or collapse might occur due to latent hæmorrhage Peritonitis and perforation were not seen in the Glasgow series although others have recorded these complications Pyloric spasm from ulcer may produce symptoms similar to those of pyloric stenosis In children past the age of infancy, according to D G W Clyne and J Rabinowitch, duodenal ulcer may closely simulate acute appendicitis

TUBERCULOSIS IN WAR TIME

REPORT OF THE MRC COMMITTEE

THE committee appointed in the autumn of 1941 by the Medical Research Council at the request of the Ministry of Health to investigate the war-time increase in tuberculosis, particularly among young women, has brought in its report [1] This differs from the council's other special reports in describing no new researches but presenting rather a critical review of available evidence In the committee's view this evidence is already sufficient to justify administrative action The findings and the recommendations based on them are as follow

FINDINGS

There has been a real increase in deaths from tuberculosis since the beginning of the war

All age-groups have been involved to some extent in the increase, and the participants up to the present have not been predominantly young women—as seemed likely early in the war—but include, particularly recently, children and the older male age-groups as well

Although there has been a slackening in the increase in tuberculosis mortality in the second year of the war—e g , in young adult females—the position is still unfavourable in relation to the prewar figures

In view of the similar, though only temporary, slackening in the rise of tuberculosis at a corresponding time in the last war, together with what is known as to the course of tuberculosis, we must be prepared for a further increase as hostilities continue

A disquieting feature of the present position is the increased mortality of children from tuberculous meningitis Measures have been indicated which should reduce the deaths from bovine infection To reduce human infection it is necessary not only to take special measures with children but also to control pulmonary disease in the adult The suggestions which have been made for the early detection, segregation and adequate treatment of the tuberculous adult should have an indirect effect in reducing infection among children

RECOMMENDATIONS

The implementing of these recommendations should be accompanied by information and propaganda both to the medical profession and to the general public

Mass radiography —Subject to limitations of apparatus the controlled use of mass radiography before, or as soon as possible after, employment should be extended, especially (*a*) in the Services (*b*) among men and particularly women entering the war industries, and (*c*) among those taking up certain other occupations A single mass X-ray examination should be carried out, where practicable, upon those already employed in certain industries—e g , munition factories As an extension of the preceding, but probably practicable to a much less extent in war-time, X-ray examinations should be repeated at regular intervals upon certain groups of the population including (*a*) employees in factories which contain large numbers of young adults, (*b*) nurses and medical students and (*c*) merchant seamen Where speed and cost dictate, the miniature method is the one of choice for mass radiography In certain circumstances it may be practicable to make use of existing full-size apparatus

Institutional accommodation for the treatment of tuberculosis is urgently required A good deal is now available but cannot be used because of lack of nursing and domestic staffs Until these staffing problems are solved, no advance can be made in institutional control of the disease

Financial provision —In view of the special character of the disease and the prolonged treatment usually required, special financial provision greater than that obtainable under the National Health Insurance scheme should be made for persons with tuberculosis

Rehabilitation should be considered an essential part of the treatment of tuberculous persons and arrangements should be made for the gradual return to industry of such patients on a basis of part-time or modified work During the period of rehabilitation a supplement to wages should be provided, in order that an adequate standard of living can be maintained by the patient and his family

Examination of all home contacts must be energetically pursued, a first examination being the chief requirement The re-examination of children under five years of age, and of young adults, is highly desirable X-ray examination, and re-examination at intervals, should be undertaken for all cases of pleurisy and erythema nodosum in young people, whether institutional treatment has been given or not

Mental hospitals —The special conditions here prevailing make it desirable that an effort should be made as soon as practicable to X ray periodically all residents of such institutions

General working conditions —It is of the first importance that continued watchfulness should be maintained upon the working conditions of young employees particularly in regard to hours of work, transport difficulties, rest periods, factory canteens and hostel arrangements, and their relation to sickness absence

Milk —The pasteurisation of milk should be extended throughout the country, and, where this is not practicable, all milk consumed by children should be boiled or dried milk should be provided

MILK IN THE HOLIDAYS

MORE and more school-children are drinking milk before the war a little over half of them were getting it and now the latest available returns show a rise to 79 8% in England and Wales and 65 1 % in Scotland Unfortunately school holidays are apt to make a break in these good habits, and the difficulties of continuing milk distribution during these gaps are considerable The Children's Nutrition Council [1] have been interested in the efforts made by local authorities to bridge the gaps

The children show varying readiness to attend school or some other centre merely to receive a third of a pint of milk, and of course it is not easy to provide staff to serve it out The Edinburgh CNC has made a special study of the situation Holiday distribution of milk had been tried in 1938 unsuccessfully, but urged by the CNC the education committee agreed to try again during the Easter holidays this year The local press published articles and, later, pictures of the children taking milk , a letter from the council was published and bills prepared by the education committee were distributed to clinics, hospitals and other centres, and the branches of coöperative and other multiple stores The time of distribution was 11 30 A M –12 noon and 32 schools were used as distribution centres—roughly a quarter of the schools under the education authority There was a fair response, the consumption per day being 27% of the usual daily school consumption or an average of 9770 children daily as compared with an average of 35,000 in term time All children under 15 were included so that the toddler could come along with the older child who had been told off to mind him

The CNC had some suggestions to make for improving results another time Thus they think the hour was too late too near dinner time Opening of a larger number of schools would have relieved congestion, and given many more children the chance to attend their own schools and avoid a longer walk than they were used to Some schools had no straws The local branch of this council, with its affiliated organisations and such bodies as women's guilds and mothers' committees could provide rotas of responsible voluntary helpers and many teachers would be prepared to give odd days in the holidays There seems, indeed, plenty of good will to help to maintain the holiday distribution, and get the milk to its target

MESSRS Southalls inform us that they are now able to supply their 'Southalamide' gauze to doctors and hospitals in 6 yd , 3 yd and 1 yd packets This sterile surgical gauze is impregnated with approximately 30% sulphonamide and the manufacturing process is designed to ensure slow absorption, and prevent the shedding of the medication Prices of this new wound dressing may be had from Messrs Southalls, Charford Mills, Saltley, Birmingham, 8

Special Articles

RECENT GERMAN VITAL STATISTICS

RICHARD M. TITMUSS

THIS paper is an attempt to place on record some recent German mortality and morbidity statistics. The data are admittedly inadequate and should be interpreted with caution, but the material is all drawn from official German publications. No attempt has been made to examine the general death-rate because, among othes reasons, the composition—either qualitatively or quantitatively—of the population at risk is not known, and because the deaths of men in the armed forces from natural causes are, as far as I know, excluded from the official reports.

MORTALITY

Infant Mortality.—For the "Great Towns" of the Reich the death-rate per 1000 live births fell steadily from 92.9 in 1929 to 60.5 in 1934. Since then the rates have been

1935	62.9	1939	59.6
1936	62.9	1940	62.0
1937	60.7	1941	58.8
1938	58.3		

The first quarter of 1942 registered the highest rate since 1933, namely, 74.1. In the four previous years the rate had been 61.3 (1938), 65.2 (1939), 69.4 (1940) and 73.5 (1941).

Ages 1–20.—As the Registrar-General for England has repeatedly shown in his annual reviews, one of the most sensitive indices to environmental conditions is mortality among infants aged 1–5 years. Before the war the death-rate in this group was steadily rising in the German great towns and the combined rate for the two years 1940–41 was higher than that during 1931–33, when the urban population of Germany was suffering severely from the effects of the world economic slump. For the 62 great towns (with populations exceeding 100,000—a total of 24½ millions) of "Greater Germany" the number of deaths in this age-group in recent years has been 5670 (1939), 6062 (1940) and 6404 (1941)—a rise of 13% over 1939, although the total population of the great towns has not changed significantly. Before 1939 the number of deaths in the 56 great towns of the Old Reich—with a fairly stable total population around 20 millions—had been rising steadily; in 1935 there were 3866, in 1936, 4307, in 1937, 4220, and in 1938, 4675. The change in the birth-rate cannot account for the rise between 1939 and 1941 because the major increment in births took place in 1934. When we compare the first 28 weeks of 1942 with the corresponding period for previous years we find that the number of deaths has risen from 3618 in 1940 to 4355 in 1942. In addition to the rise of 13% between 1939 and 1941 there has been a further increase during the first 28 weeks of 1942 of 20% over 1941. The winter cannot be blamed for this increasing mortality because, from the point of view of health, climatic conditions were not severe.

Similarly with school-children, for we find that the deaths have risen from 4336 in 1939, to 4337 in 1940 and 4880 in 1941. On the top of this record number of deaths in 1941 for the age-group 5–15 a further increase of 22% has occurred during the first 28 weeks of 1942 over the corresponding period for 1941.

In the age-group 15–20 mortality has increased by 20% (the first 28 weeks of 1942 over 1939). This rise, moreover, excludes the deaths of young men in the armed forces both from disease and hostilities. The deaths in the age-groups quoted also exclude air-raid casualties.

SPREAD OF INFECTIOUS DISEASES

Contributing to the increases in mortality among children scarlet fever deaths in 1941 reached 1327, the highest number of deaths in any single year since at least 1929; the previous record number in any one year since 1929 was 635 in 1940 and 445 in 1939. Diphtheria and whooping-cough mortality has also risen, the combined total for 1940–41 being 7005 as against 4862 for 1937–38. Between 1932 and 1937 mortality from both diphtheria and scarlet fever among children under 15 rose steadily, the increase in both cases being roughly 50%.

In addition to the rise in mortality there has been a great increase in the number of new cases of infectious diseases; the numbers in all areas of the Old Reich were

Year	Diphtheria	Scarlet fever	Whooping-cough	Dysentery	Trachoma
1936	149,973	125,679		4816	625
1937	146,733	117,544		7545	697
1938	149,627	114,243		5265	533
1939	143,585	129,495	78,941	6190	652
1940	142,058	138,759	126,994	12,790	2979
1941	173,052	247,744	93,694	8641	2770

These increases are striking enough but the first 28 weeks of 1942 show a further rise over the corresponding period of 1941. For all areas of "Greater Germany" the number of diphtheria cases has risen by 42,000 to 130,000, while scarlet fever cases are up by 101,000, to 238,000.

TUBERCULOSIS

Tuberculosis is always a sensitive barometer of the *extent to which a community is caring for its people.* New cases of respiratory tuberculosis in all areas of the Old Reich have been as follows

	Quarter—			
Year	I	II	III	IV
1935	15,649	16,200	18,186	10,341
1936	15,835	16,095	18,218	10,579
1937	16,881	17,787	15,034	13,868
1938	16,052	16,441	14,233	13,694
1939	19,431	18,448	15,816	14,195
1940	17,096	21,778	17,514	16,879
1941	20,660	24,155	20,266	16,962

Taking the averages for the years 1935–38 as a base-line the increases amount to: 1941, first quarter 28%, second quarter 45%, third quarter 23%, fourth quarter 40%, all quarters 34%. For other forms of tuberculosis the 1941 notifications record a rise of 92% over 1939 (before this year cases were not notified). The three years 1939–41 have produced 40,000 *additional* new cases of respiratory tuberculosis. Just as morbidity has been rising so has mortality. The mortality from all forms of tuberculosis at all ages in the great towns of "Greater Germany" were as follows (rates per 1000 total population)

	Quarter—				
Year	I	II	III	IV	Total
1939	0.76	0.72	0.56	0.61	0.66
1940	0.82	0.81	0.63	0.63	0.73
1941	0.84	0.82	0.69	0.64	0.76
1942	0.88				

It is worth noting that the rate for the first quarter of 1942 is higher than that of the years 1932 and 1933. A considerable rise is again revealed when we examine the death-rate from all forms of tuberculosis in two large groups of great towns. Group 1, the Rhine and Westphalia, comprises 19 large towns such as Cologne, Essen, Dortmund, Dusseldorf, Duisburg, Gelsenkirchen and others, with a total population of 5½ millions. Group 2 relates to 14 great towns (total population nearly 5 millions) in Silesia, Saxony and South Germany, such as Leipzig, Dresden, Chemnitz, Breslau, Nuremberg and Munich. Taking the years 1936–38 as a base-line we find that weekly deaths in the (by now) heavily bombed towns of group 1 rose by 10% in the first quarter of 1942 and by 20% in the second. In group 2 the increases are 12% and 16% respectively.

When it is remembered that all these war-time statistics relate to civilian deaths only and that many patients suffering from tuberculosis will have been removed from the towns in western Germany it may well be that the true increase in this disease is much higher than is estimated in this paper.

These figures do not, of course, cover a very large field but they do comprise, in the main, significant indices. Moreover, the tuberculosis statistics may considerably understate the actual situation, particularly in western Germany, not only because of the effects of air-raids but because of the removal of some millions of young men from the total population at risk.

TUBERCULOSIS IN WAR TIME

REPORT OF THE MRC COMMITTEE

THE committee appointed in the autumn of 1941 by the Medical Research Council at the request of the Ministry of Health to investigate the war-time increase in tuberculosis, particularly among young women, has brought in its report[1] This differs from the council's other special reports in describing no new researches but presenting rather a critical review of available evidence In the committee's view this evidence is already sufficient to justify administrative action The findings and the recommendations based on them are as follow

FINDINGS

There has been a real increase in deaths from tuberculosis since the beginning of the war

All age-groups have been involved to some extent in the increase, and the participants up to the present have not been predominantly young women—as seemed likely early in the war—but include, particularly recently, children and the older male age groups as well

Although there has been a slackening in the increase in tuberculosis mortality in the second year of the war—e g , in young adult females—the position is still unfavourable in relation to the prewar figures

In view of the similar, though only temporary, slackening in the rise of tuberculosis at a corresponding time in the last war, together with what is known as to the course of tuberculosis, we must be prepared for a further increase as hostilities continue

A disquieting feature of the present position is the increased mortality of children from tuberculous meningitis Measures have been indicated which should reduce the deaths from bovine infection To reduce human infection it is necessary not only to take special measures with children but also to control pulmonary disease in the adult The suggestions which have been made for the early detection, segregation and adequate treatment of the tuberculous adult should have an indirect effect in reducing infection among children

RECOMMENDATIONS

The implementing of these recommendations should be accompanied by information and propaganda both to the medical profession and to the general public

Mass radiography —Subject to limitations of apparatus, the controlled use of mass radiography before, or as soon as possible after, employment should be extended, especially (*a*) in the Services, (*b*) among men and particularly women entering the war industries, and (*c*) among those taking up certain other occupations A single mass X-ray examination should be carried out, where practicable, upon those already employed in certain industries—e g , munition factories As an extension of the preceding, but probably practicable to a much less extent in war-time, X-ray examinations should be repeated at regular intervals upon certain groups of the population including (*a*) employees in factories which contain large numbers of young adults, (*b*) nurses and medical students, and (*c*) merchant seamen Where speed and cost dictate, the miniature method is the one of choice for mass radiography In certain circumstances it may be practicable to make use of existing full size apparatus

Institutional accommodation for the treatment of tuberculosis is urgently required A good deal is now available but cannot be used because of lack of nursing and domestic staffs Until these staffing problems are solved, no advance can be made in institutional control of the disease

Financial provision —In view of the special character of the disease and the prolonged treatment usually required, special financial provision greater than that obtainable under the National Health Insurance scheme should be made for persons with tuberculosis

Rehabilitation should be considered an essential part of the treatment of tuberculous persons, and arrangements should be made for the gradual return to industry of such patients on a basis of part-time or modified work During the period of rehabilitation a supplement to wages should be provided, in order that an adequate standard of living can be maintained by the patient and his family

Examination of all home-contacts must be energetically pursued, a first examination being the chief requirement The re-examination of children under five years of age, and of young adults, is highly desirable X-ray examination, and re-examination at intervals, should be undertaken for all cases of pleurisy and erythema nodosum in young people, whether institutional treatment has been given or not

Mental hospitals —The special conditions here prevailing make it desirable that an effort should be made as soon as practicable to X ray periodically all residents of such institutions

General working conditions —It is of the first importance that continued watchfulness should be maintained upon the working conditions of young employees, particularly in regard to hours of work, transport difficulties, rest periods, factory canteens and hostel arrangements, and their relation to sickness absence

Milk —The pasteurisation of milk should be extended throughout the country, and, where this is not practicable, all milk consumed by children should be boiled or dried milk should be provided

MILK IN THE HOLIDAYS

MORE and more school-children are drinking milk before the war a little over half of them were getting it and now the latest available returns show a rise to 79 8% in England and Wales and 65 1 % in Scotland Unfortunately school holidays are apt to make a break in these good habits, and the difficulties of continuing milk distribution during these gaps are considerable The Children's Nutrition Council[1] have been interested in the efforts made by local authorities to bridge the gaps

The children show varying readiness to attend school or some other centre merely to receive a third of a pint of milk, and of course it is not easy to provide staff to serve it out The Edinburgh CNC has made a special study of the situation Holiday distribution of milk had been tried in 1938 unsuccessfully, but urged by the CNC the education committee agreed to try again during the Easter holidays this year The local press published articles and, later, pictures of the children taking milk, a letter from the council was published and bills prepared by the education committee were distributed to clinics, hospitals and other centres, and the branches of cooperative and other multiple stores The time of distribution was 11 30 A M -12 noon, and 32 schools were used as distribution centres—roughly a quarter of the schools under the education authority There was a fair response, the consumption per day being 27% of the usual daily school consumption, or an average of 9770 children daily as compared with an average of 35,000 in term time All children under 15 were included so that the toddler could come along with the older child who had been told off to mind him

The CNC had some suggestions to make for improving results another time Thus they think the hour was too late, too near dinner time Opening of a larger number of schools would have relieved congestion, and given many more children the chance to attend their own schools and avoid a longer walk than they were used to Some schools had no straws The local branch of this council, with its affiliated organisations and such bodies as women's guilds and mothers' committees could provide rotas of responsible voluntary helpers, and many teachers would be prepared to give odd days in the holidays There seems, indeed, plenty of good will to help to maintain the holiday distribution, and get the milk to its target

MESSRS Southalls inform us that they are now able to supply their 'Southalamide' gauze to doctors and hospitals in 6 yd , 3 yd and 1 yd packets This sterile surgical gauze is impregnated with approximately 30% sulphonamide and the manufacturing process is designed to ensure slow absorption, and prevent the shedding of the medication Prices of this new wound dressing may be had from Messrs Southalls, Charford Mills, Saltley, Birmingham, 8

In England Now

A Running Commentary by Peripatetic Correspondents

I HAVE just been to a war-time christening and it happened this way. The matron of our largest nursing-home had seen it grow into a well-equipped and very efficiently run institution of some 20 beds when the bombshell fell. Quite literally, too, but luckily at some little distance, so that owing to the precautions taken no-one was hurt. Nor was the house badly damaged, as damage goes in our much bombed town, but its days were over as a nursing-home; windows there were none, doors were few and the roof resembled a colander. And, as I told her next morning when we surveyed the wreckage, how could I send her patients if the rooms weren't even dusted? True, the dust was mainly two inches of ceiling plaster, but from whatever angle you look at it, air-raids are a dirty business. With her usual indomitable pluck, matron took the best available house in the neighbourhood, alas with far less than her 20 beds, and there, when our patients are lucky enough to secure an empty bed, we gladly make the 8-mile journey. In her more spacious country surroundings she decided to keep chickens, and today the first four hens had arrived, ready, we hope, to make some amends for that egg dropped by the Luftwaffe. "I'm christening them today," she said, "and of course in these days we think first of Winston Churchill, so they are to be Blood, Tears, Toil and Sweat." Though perhaps the chicken world manages those things more easily, I thought of the curse laid on the daughters of Eve and how appropriate the names were for the most industriously maternal of all our domestic animals.

* * *

They had a sing-song in the hostel in which I live, and I am ashamed to say I didn't go. But it was difficult not to hear them singing, and with each song memories I did not wish for came flooding into my mind. Presumably the psycho-auditory centres keep accurate copies of those scenes which the psycho-visual centre and the frontal lobes have long since and carefully repressed. Normally the past does not distress me in the least; I have carefully sifted out for consciousness those scenes which make for happiness. But hearing Auld Lang Syne brings detailed pictures of the other times I have sung it, of the people at school, at Oxford, at a Christmas dance, whose acquaintance, since I am unlikely to renew it, it would perhaps have been better to forget for good. Smells are as bad. Walking along a most innocent road the other day I was first assailed with a momentarily irrepressible longing for a house on an estuary in Wales and then within twenty yards for pine trees and honeysuckle in Georgia. But on the whole there are more smells than songs, and it is safer to have an open nose than an open ear; though there again, I am thankful to say, they change the tunes so often that it is only the very best—*Donkey Serenade* and *Begin the Beguine* and *Waltzing Matilda*—which last long enough to repeat the memories of a few years back. Such few as there are fill me with admiration for the memory-repression mechanisms of the other parts of my brain. I can only think of one song whose immediate memory-associations are wholly good—*Steal away*. It reminds me of a time when an old lady had died, and a thousand negroes sat on the lawn of her plantation singing that song with tears running down their cheeks, so beautifully that she must surely have heard. For the vividness of that one memory I can forgive my psycho-auditory centre a lot.

A country practitioner whom I met last month showed me the records of 20 patients who had developed hypertension within two months to ten years of hysterectomy. "Why don't you publish them?" I asked. "Probably I should be told that my observations were cold potatoes, Blitz having recorded 500 cases in 1921 and Krieg having written a book about it." In the bright new world I hope they will have a room or two in Health and Hygiene House where such reports from the front line of medicine can be examined and sifted. Possibly also they will have their own broadcasting station. I seem to hear the droning voice of Pontifex Maximus FRCP giving one of his bed-time talks to GPs: "— is the most likely theory of hyperpiesia. Goldblatt found that by constricting the renal arteries of animals he produced hypertension, then Wilson and Byrom went on to show that they could get the same result by constricting one artery. That it isn't only a renal threat that causes a heightening of the blood-pressure was pointed out by Raab, who recalled that it was experimentally produced by restricting cerebral blood-supply. It is as though Dame Nature said, 'The fate of a vital tissue is at stake, we must give it more blood.' As in shock she is quite willing to run risks with the whole in order to save a vital part. And the poor, blind old dear doesn't know when to leave off. Probably she is encountering a condition that was so rare in the first million years or so of her wet-nursing of us that it wasn't worth bothering about. Why she should translate a hysterectomy as a threat to what she must regard as the most vital organ of all, I'll leave you to guess. It would be interesting to know if constriction of the spermatic arteries also raises the blood-pressure. If this theory is right it most certainly should, and I feel in my bones that mine would. How does it act? Heaven alone knows, but probably by the old primitive mechanism of a chemical acting on the autonomic and the autonomic stimulating the production of the chemical, a circular reinforcement. Of course this is all theory. Probably it is impossible to record any events in the natural world truthfully. In fact truth as a static, unchangeable reality—apart from those man-postulated artefacts, words and figures—is a human misconception. There is no such thing as truth, everything is changing, moving, angled and relative. But it makes a very workable hypothesis to say that truth exists. It might be called 'The Master Hypothesis.' So with this hypothesis of the cause of hypertension, the truth is But I see my time is up. Good-night GPs. Good-night."

* * *

A butterfly orchis in a vase in front of me was picked ten days ago and seems unchanged; all the pollinia are in place. Others in the copse have been fertilised by long-tongued moths, the only insects which are capable of doing it, and are starting to wither. I think the youthful appearance of many single middle-aged people may be on the same parallel. Thanks to this infinite patience and this cold-storage of charm not many flowers, only some of the more highly specialised, are, I fancy, born to blush unnecessarily in nature. Another display of the same qualities is seen in courtship. Any reflective watcher of animal life must often have been struck by this contrast: the length of it, the elaborate ritual, for which so many dress up or undergo structural change, prepare for months, sometimes their whole lives, all this, and then the rapid, hurried, darkened, rarely seen consummation. Marie Stopes and others have pointed out how prolonged love-play conduces to fertility, and we old country practitioners know how the lad and lassie in Love Lane who struggle at length and victoriously against the scowling gods of propriety, the frowning powers of Church and State, the angry parental deities, nearly always produce a bonny babe, whereas the suburban know-all who treats his consummation as an afterthought to a wash and brush-up goes bald and childless. Incidentally contraceptives may stop fertility in more ways than in preventing spermatozoa getting to the ova. My point is this. Prolonged courtship, the aim of which is that the one man should meet the only woman in the world or as near to this novelists' ideal as nature can manage—a discarding of unsuitable genetic combinations, a long process of selection which is abandoned in times of racial stress—demands a contradictory attitude of mind. It must be one that is so intensely attracted that his or her whole mind is ruled by that attraction, and yet at the same time inhibited, in the human mind by various creeds, customs and codes (I wonder what form this takes in the mind of the rabbit—The Big Bad Buck—The Weasel Banshee?), lest consummation come too early. This surely is one of the bases from which one should start the study of sexual taboo.

* * *

"Well," said Helen with a sigh, "I suppose it's got to be done—shall we make a start?" I rose reluctantly to my feet and together we went out to the garage, for the task in hand was that which has faced so many of us lately—laying up the car. Dear old George. I felt a fresh uprising of regretful affection as I gazed on his war-worn paint, but, as Helen said, it had to be done, and so we got to work. I sorted tools and greased lamps and bright parts (vide advice in the daily press), while Helen applied herself to cushions and upholstery with the energy of a terrier at a rabbit hole. For a time we worked in silence, but for the whirr of the vacuum cleaner, and I knew that her thoughts were, like mine, with *all* the occasions in which George had played so large a part: not only his stalwart help in my professional work, but those happy care-free holidays, our annual outings to Wimbledon and Twickenham and scores of others. Oh, well some day. Suddenly the roar of the vacuum stopped and Helen emerged from the car holding out a small piece of green cardboard. "Look at this," she said, "it was behind a cushion." It was a car-park ticket for a point-to-point meeting in April '39, and my thoughts raced back over the shadowed years between. I remembered it so well, as lovely a day as April ever provided and as we walked round the course before the first race the larks were singing and Spring was everywhere. There was the usual cheerful crowd of men and girls in tweeds, children home for the holidays, country folk complete with perambulators, raucous-voiced tipsters, horsey-looking men, picnic luncheons laid out behind the cars, and, incidentally, the racing. It was a *good* day, and I remembered, too, Helen's annoyance at not having backed a horse called "Peter's Pet," which won at long odds. She knew nothing, of course, about its capabilities, but she had just met a young friend called Peter with his very new fiancée and that should have been a good and sufficient reason, in her view, for backing it. Suddenly she laughed. "It was broken off soon after," she said, so I knew that her memory was working on the same lines as mine. Presently George's toilet was completed, and shrouded in dust sheets he was left to rest until happier days. So now, to save petrol and rubber, I go my rounds in Helen's little 8-h.p. bus, and she does her share by carrying laden baskets up the mile of hill from our nearest shops.

* * *

Housemen lack none of the courage and initiative of their predecessors, at any rate mine doesn't. His interest ranges over the whole field of medicine, with a strong bias towards psychiatry. One patient had a very severe tic, which he asked permission to treat by psychotherapy. Next day I asked how it was progressing, and was told that after two hours' intensive treatment he found he had been talking into her deaf ear. Later, we admitted a diabetic for observation who appeared to be developing psychiatric symptoms in addition. He confessed to having taken his usual 30 units of mixed insulin that morning, though in his apathy he did not mention the unusual extra dose which the HP gave him that evening. The comments of those called up to treat the hypoglycæmic convulsions at 3 A.M. temporarily flattened the HP, but the outcome left him on the pinnacle of success, for the morning found the patient pale, shaken and a little distrait, but in his right mind. Some days later a consulting physician came down to see a case suspected of being glandular fever. He is of the younger school, with a deliberate manner. Having given his opinion he said he felt himself a particular authority on glandular fever, since he was just recovering from it, and he proceeded to recount some of the more unpleasant symptoms.

Physician. "All the glands of the body tend to enlarge, including the epitrochlears."—HP. "Were your epitrochlears enlarged, Sir?"—Phys. "Yes, they were."—HP. "I thought they *only* enlarged in syphilis, Sir?"—Phys. "I can assure you they sometimes enlarge in other conditions as well, mine were enlarged, and I had glandular fever." Here the HP lapsed into silence, still looking unconvinced, but he brightened later and returned hopefully to the attack.

HP. "Did you say that the WR was sometimes positive in glandular fever, Sir?"—Phys. "I did."—HP. "Was your WR positive, Sir?"—Phys. "Sorry to disappoint you, Mr. Smith, but my WR was negative, and I did *not* have syphilis, but glandular fever."

Here I suggested moving on to another case.

SPORTSMAN'S LAMENT 1942

If I had plenty of time to spare
And petrol enough to get me there,
And if I could buy some cartridges
—Wouldn't I shoot some partridges!

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS, M.P.

THE debate on the coal situation and the demand for rationing have brought us up against one of the most difficult war-time problems for industry and one of the most uncomfortable problems for the ordinary citizen. There is a big deficit, Mr. Gwilym Lloyd George put it at 11 million tons, between production and consumption. It may be more. The Minister thinks that the gap can be bridged. But the House as a whole is sceptical. On output Mr. D. Grenfell, former Secretary for Mines, warned the Minister not to weigh his coal until it was in the bag.

From the point of view of the health, and convenience, of the country the Government did well to announce priority in distribution for the households taking about 1 cwt. a week. If this is maintained, and it depends *not only on general distribution but on local distribution* by retailers, some of the worst difficulties will be overcome. For nothing would be more disastrous than to subject the people of these islands in the fourth winter of war to an ordeal by cold. Mr. Grenfell said you could not make war with cold feet. What is equally important perhaps is that you cannot get good production on cold dinners and bad cooking. Nor can you maintain good health. These aspects of the matter are very much in the minds of members but received less attention in debate than the conditions in the coal industry itself on which so much depends. Major Lloyd George is a judicially minded man whose ambition it was said, before the war, was in the direction of the speakership of the House rather than that of minister. And it is perhaps lucky that what is one of the most difficult ministries has him at its head.

Whatever the decision of the Government may be, whether rationing is adopted or voluntary economy aided by slogans and reinforced by limiting orders, the coal industry itself is becoming more organised. Mr. Tom Smith, parliamentary secretary of the ministry gave a good deal of information about the new medical service. The present staff of one medical officer at the HQ of the ministry is to be increased by another nine, making ten in all of whom two will remain at HQ and eight posted to the coal-producing regions into which the country is divided. The duty of each regional MO will be to deal with medical services at the pits, away from the pits, and with the checking of medical certificates. The provision of first-aid organisation in the pits, and the provision of ambulances, is to be brought up to date. That the provision of these services still leaves some work to be done is a serious comment not only on the humanity but on the commonsense of colliery organisation. The prevention of occupational diseases and the promotion of physical fitness are other sides of the problem. Nystagmus is declining, largely, so the Parliamentary Secretary said, because there has been extra illumination. The provisions in operation in respect of silicosis are to be extended to conditions set up by other agents than silica and grouped under the term pneumokoniosis. In some pits there are more boils and carbuncles than in others and another industrial disease claiming attention is dermatitis. The regional MO will be expected to go down pits and investigate for himself and he looks like having plenty to do.

The regular inspection of juvenile workers is not proposed for the present, on account of shortage of staff, but a preliminary inspection on entry is to be the rule. Service away from the pits comprises panel treatment and hospital treatment both as in- and outpatients. The expenses of a miner attending for outpatient treatment, if sent by his doctor, are in future to be paid in full. A rehabilitation centre is being set up in Scotland and the Mansfield rehabilitation centre is accepted as a good type of institution. Certificates presented with an application to leave the industry on medical grounds will be lodged with the regional MO and arrangements made for checking the numbers and local origin of the certificates. Regions vary greatly in the numbers certificated under this head, but in one quarter there were just under 20,000 applications to leave the industry based on medical certificates. Absenteeism is to be treated, if it is found to depend on any medical disability, and to help with this the question of maintenance of the man and his family during treatment is being given careful consideration. Quite clearly the scope of the mining medical services is wide and difficult of exact definition at present. But miners are to be looked after as never before and the question of accidents considered as never before. The country is at last realising the value of its miners. Absenteeism is not a new problem and Mr Smith quoted from a Scottish Act of Parliament in 1641 as follows: "Coal hewers in Scotland doe ly from their worke at Pasch Yule Whitsunday and certain other tymes of the year which was of great offence to God and prejudice to the coal-master." We are beginning to get away from that attitude now—but perhaps because of our past indifference we shall be cold this winter.

* * *

To turn from the coal debate in the Commons to the debate in the Upper House on Lord Strabolgi's magazine article was to go from a grim battle-front to a panoplied display of dashing commando tactics. Lord Lovat, in uniform, spoke as if to his men. He called Strabolgi's criticisms bunkum and asked whether apprenticeship to the technical trade of soldiering was waste of time. "Tell that to the A E U," he said. He hotly resented the accusation that army officers were drawn from a class of British junkers. Strabolgi's reply showed that he wrote his article at the request of Quentin Reynolds to counter unfair criticism of the British Army in the U S A and quoted his first sentence: "Fundamentally nothing is wrong with the British Army." In withdrawing his motion for papers, which is the procedure in the Lords when a debate has achieved its purpose, Lovat said, "I have had great pleasure in crossing swords with Lord Strabolgi." And so a colourful debate ended with members of the Commons present considering that Lovat had done very well and Strabolgi put up a very good apologia. How unfortunate it is that no constitutional arrangement exists by which a brilliant soldier could come and talk to us in the House of Commons—although of course he could get elected—probably as "Independent."

QUESTION TIME

Food for Occupied Territories

Mr D M FOOT, parliamentary secretary to the Ministry of Economic Warfare, replying to Sir THOMAS MOORE, said: While exact statistics are not obtainable, I fear there can be no doubt that an abnormally high death-rate prevails among Greek children. It is a reasonable inference that this is partly due to scarcity of milk and fats. Before the war Greece was substantially self supporting in milk, and a very large exporter of olive oil. My information is that both these commodities have been requisitioned or otherwise acquired on a considerable scale by the occupying authorities, who must therefore be held responsible for the present acute shortage. The Swedish scheme for the importation and distribution of wheat from Canada has only been in operation for a short time. I cannot give any fresh undertaking as to the future, at least until the results of this experiment are known. Statements in the press that milk was available in South America and that it was impossible to get it to Greece owing to the refusal of navicerts by the British Government were misleading. He understood that the supplies of milk were not yet available and the Government had received no applications for navicerts.

In answer to a further question Mr FOOT said: While information about conditions in the Channel Islands is necessarily incomplete, the evidence available suggests that although there is a shortage of food in the islands by comparison with this country, and an almost total lack of certain particular products, the effect of the deficiencies has not been such as to impair the general health of the inhabitants.

Mr A EDEN, replying to Mr V BARTLETT, said: Recent reports show that while conditions in the internment camps in Hong Kong have to some extent improved since the early days, the general health of the internees has seriously suffered from lack of proper food and medicines. A sum of money has been allocated from official funds and has been transferred through the Swiss Government to the International Red Cross delegate at Hong-Kong. But owing to shortage of local supplies which can be purchased by the internees, only temporary relief can be afforded by this method. The Japanese authorities have refused to allow special relief ships for prisoners of war and interned civilians to be sent to Hong-Kong and other territory occupied by them; they have, however, agreed that food, clothing and medical comforts might be sent by the ships on which British and Japanese officials are being exchanged on their return voyage. This means that unless and until the Japanese Government alter their decision, the scale on which it is possible to send relief supplies is strictly limited. Full advantage was taken of the exchange ships and the total amount of the supplies shipped in them was about 4000 tons. Arrangements have been made for an equitable proportion of these supplies to be landed at Hong-Kong, and the first ship is due to reach Hong Kong within the next few days.

Scientific Advisory Committee

Mr IVOR THOMAS asked the Lord President of the Council who were the members of the Scientific Advisory Committee of the War Cabinet and what were the duties of this committee.—Sir JOHN ANDERSON replied: The scientific members of the committee are Sir Henry Dale, MD, PRS, Prof A V Hill, and Prof A C G Egerton (joint secretaries of the Royal Society), Sir Edward Appleton, secretary of the department of Scientific and Industrial Research, Sir Edward Mellanby, MD, secretary of the Medical Research Council, Prof W W C Topley, MD, secretary of the Agricultural Research Council. The functions of the committee are: to advise the Government on any scientific problems referred to it; to advise Government departments, when required, on the selection of individuals for particular lines of scientific inquiry or for membership of committees on which scientists are required; to bring to the notice of the Government promising new scientific or technical dvelopments which may be of importance to the war effort. Replying further to Mr THOMAS, Sir J ANDERSON said he had sometimes wished that departments would make more use of the services of this committee. It had been of great assistance to the Government as a whole and to departments.

Miners' Diseases

Mr JAMES GRIFFITHS asked the Minister of Fuel and Power whether the incidence of industrial diseases among coal miners was increasing and if he would give figures showing the increase in the number of cases of dermatitis and the reasons for the increase.—Major LLOYD GEORGE replied: There has been some increase in certain categories of disease and some decrease in others during recent years. For reasons which are at present obscure the number of cases of dermatitis among miners certified by examining surgeons for purposes of Workmen's Compensation has increased from 224 in 1937 to a provisional figure of 571 for 1941. As the problems of dermatitis also arise, and to a greater extent, in the case of factory workers, I am consulting with the Minister of Labour and National Service as to the best lines of investigating the matter more closely.—Mr GRIFFITHS: Will the Minister bear in mind that there is considerable opinion among the medical men who serve in the mining areas that this increase of dermatitis, which is very serious, is due to certain deficiencies in the diet, and will he have immediate inquiries made into that point?—Major LLOYD GEORGE: I have had inquiries made into one section of diet to which the hon. member has previously referred. He will not be surprised to hear that medical opinion is exactly the opposite. There has been an increase which has not been confined to the mining industry nor to the war years. I am making the most careful inquiries.

Midwives and Nurses

Mr E BEVIN informed Mr R DE LA BERE that he already had powers under the Defence (General) Regulations to direct midwives or nurses at present otherwise engaged into branches of the profession where there were shortages. He was in consultation with the Minister of Health on the general question of supply and employment of midwives and nurses.

Chiropodists in the Army

The Secretary of State for War informed Mr JOHN DUGDALE that, in view of experience which suggested that more skilled treatment might be desirable, he was now considering the attachment of fully qualified chiropodists to field medical units in the army.

VAD Committee

In reply to a question Sir J GRIGG stated: Arrangements for setting up a committee "to consider the scope and method of employment of Mobile Voluntary Aid Detachments by, and their relationship to, the Services ' have just been completed. Colonel W Elliot has agreed to be chairman , and a representative has been nominated by each of the three Service departments, the Ministry of Health the Ministry of Labour and National Service the British Red Cross Society, the Order of St John of Jerusalem and the Council of County Territorial Associations The chairman has suggested that Mrs J L Stocks, who was a member of the Committee on Amenities and Welfare in the Women's Services, should also serve

Medical Women Officers for WRNS

Sir ERNEST GRAHAM LITTLE asked the First Lord of the Admiralty whether he would consider the desirability of appointing medical women to serve in stations in naval commands as in other of the fighting services —Mr ALEXANDER replied It has already been decided to appoint a woman naval surgeon at one of the WRNS establishments and other appointments are under consideration

Air-raid Casualties

During the first three years of war 47,305 civilians were killed and 55,658 were injured and detained in hospital due to air raids on the United Kingdom - The figures for Greater London only included in these totals are 20,110 and 26 071 respectively (Mr H MORRISON in reply to Mr H BROOKE)

Addition of Calcium to Bread

Mr J H MARTIN asked the Parliamentary Secretary to the Ministry of Food whether in view of the diversity of medical opinion as to the effect of adding calcium to bread, he would consider offering two loaves to the public, one containing calcium and one without —Mr W MABANE replied My department is guided in all matters affecting medical questions and public health by the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council As this committee strongly advised that calcium should be added to all flour and that there should not be an alternative loaf containing no added calcium, the Minister sees no reason for adopting the suggestion

Diphtheria Immunisation

Mr BROWN, replying to a question, said The returns regarding diphtheria immunisation obtained from local authorities as a whole at Sept 30, 1941 showed that between Jan 1, 1940, and that date the number of notifications in England of diphtheria in children under the age of 15 was approximately 51,700, and that approximately 2380 of these children had received a course of immunisation. In the same period the total number of children immunised under local authority arrangements in England was approximately 1,889,000 By the end of June, 1942, this number had increased to close on 3 million

Insulin and Needles for Diabetics

Mr J J TINKER asked the Minister of Health if he was aware of the hardship caused to diabetic patients by the increased prices of insulin and needles which they must have , and if he would consider means to prevent these continued increased prices so as to place them within reach of all who needed them —Mr BROWN replied I am aware that prices have increased, but having regard to the free provision of insulin and the necessary appliances for administering it under the National Health Insurance and public-assistance schemes, I do not think that there is a case for any special measures to prevent any increases which may be warranted by the conditions of production.—Mr TINKER Could not something be done for people in need of insulin outside the societies mentioned ?—Mr BROWN I understand that Mr G Griffiths has been discussing the matter with the Parliamentary Secretary —Mr GRIFFITHS Does the Minister know that the discussion has failed badly, and is it not time that the Minister did something for people suffering from diabetes ? There is a person in my division taking 90 units a day, and she cannot get a penny piece I hope the Minister will rise to the occasion. If he subsidises the price of insulin that will do something towards it —Mr BROWN That is a point that we are looking at now —Mr GRIFFITHS I want the Minister to do it, and not to look at it

Medical Schools Committee

Mr BROWN informed Sir ERNEST GRAHAM-LITTLE that the universities and medical licensing bodies were not consulted as to its composition and subjects of inquiry before the interdepartmental committee on medical schools was formed.

Letters to the Editor

TIME OF UNION IN FRACTURED TIBIA

SIR,—The article by Burns and Young in the *Lancet* of Sept 12 brings before us again the necessity for defining what we mean by union and when we are entitled to say that union has taken place in x weeks or y months Burns and Young do clarify this quotient but I still feel that " union " is a loosely applied term In their recent textbooks on fractures neither Watson-Jones nor Perkins sets down any criteria on which to form the opinion that any particular fracture has united at any given time Perkins writes " Experience tells us that a fracture will unite and consolidate in a certain time (See page 23 for time-tables) " This is hardly a clinical or physiological definition Surely if we are to form comparisons we must have some standard from which to assess when union has occurred Otherwise a fracture which one surgeon would consider united might be deemed not fully united by another I suggest some such classification as the following

Signs of union may be (*a*) clinical, (*b*) radiological

Clinical—Rigidity of the fragments after x weeks Loss of tenderness on percussion No tendency to angulate under strain in use

Radiological—Callus Well calcified Fracture Line Disappearance of, Growth of trabeculæ across

Bone Substance Changes in

1 Callus
   Absorption of excess
   Moulding of by the periosteum
2 Osteoid tissue
   Osteogenesis of endosteal callus
   Disappearance of the osteoporosis of the bone ends at the site of fracture
3 Bone Restoration of the normal density, structure and detail at the site of fracture and for a short distance above and below

Some standard on these lines would render comparison of surgeons' tables on union more equitable

Harley Street, W 1   G O TIPPETT

SIR,—Some of the facets of the problem of the rate of union of the fractured tibia presented by Burns and Young in your issue of Sept 12, and more critically illuminated by your annotation on the subject, prompt me to try and add a few more, as the subject still seems to be exciting interest

In 1840, talking of fractures of both bones of the leg, Malgaigne says, " The callus forms in thirty five to forty days, and we may take off the apparatus, and let the patient move his leg in bed without any inconvenience resulting "[1] In 1860, Hamilton in America states, " The average period of perfect union in 29 cases, including those in which union was delayed by extraordinary causes beyond the normal time, was forty days , the general average under ordinary circumstances may be stated at about thirty days "[2] In 1750 Heister gives thirty to fifty days as the period of union,[3] and this period seems to be the generally accepted one at least till 1900, when an inquiry was circulated among British hospitals by the BMA and produced substantially similar figures[4]

After this period, among a multiplicity of authors, the period lengthens to " five to eight " weeks Thus Matti in 1931 states, " Solid healing of fractures of the shafts of both leg bones takes five to eight weeks , it occurs more quickly the younger the patient and the better the position of the fragments Transverse fractures heal more slowly than oblique, apparently because the callus forming zone is less disturbed "[5] In 1938 Böhler states, " Fractures with little displacement heal in eight weeks, but with greater displacement take ten to twelve weeks "[6] This is the figure I obtained in uncomplicated cases in a fracture clinic before the war

[4] Bennett W H *Brit med J* 1900, ii.
[5] Matti, H Knochenbrüche, Berlin 1931 p 828
[6] Böhler L Die Behandlung der Frakturen, Vienna, 1938, vol 2, p 1194

We are thus prompted to ask what has caused the delay from consolidation in six weeks to consolidation in eleven weeks, between 1840 and 1940? In my opinion it is chiefly due to the use of X rays for the diagnosis of union If a series of cases is taken, and the time of clinical union tested against the time for radiological union, a period of five weeks will be found on the average to have elapsed With the advent of X rays as a criterion of union (and this did not become of value or was generally employed till after 1920) we started to be more careful in letting our patients up, with apparent slowing in the rate of union I think the first conclusion we must draw is that we should rely more on clinical evidence of consolidation A second factor is undoubtedly the greater use of plaster, for, if the splint cannot be frequently removed to estimate union, it tends to stay on longer than necessary, and the average figures rise I am not convinced that delay is any more than reflexion of these facts; in a recent small series of military cases of a similar type to Burns and Young's later group, I find union to have averaged eleven weeks

The comparison of such statistics is however rendered rather valueless by a lack of agreement as to what constitutes a legitimate complication delaying union Like Burns and Young, I have noted the delay when there was an accompanying fracture of the femur, but no mention was made in their paper of the effect of the double spiral, or double oblique fracture which separates a triangle of bone, and in my experience slows down the period of union by five to seven weeks The importance of local skin infection, apart from actual infection of the bone, was not mentioned, and many cases nowadays have burns or abrasions together with their fracture Nor is the statement "apposition approximately equal" a sufficient yardstick for comparison, as the displacement before reduction is surely, from this point of view, as important as the position after reduction, and may well determine when a plaster may be applied In short, I feel that the rate of union of fractures has remained unaltered, and that if we are keeping our cases longer in hospital it is due to a higher incidence of complicated fractures—if we exclude maltreatment, and with Burns and Young I am in hearty agreement about the danger of overtraction and prolonged traction in causing delay

As a last point it is interesting to note that the protagonists of absolute immobilisation are the protagonists of early walking plasters I find it impossible to believe that any plaster, however skilfully applied, totally abolishes movement at the fracture site, and I think the case for slight movement at the fracture site hastening union, provided it does not produce a shearing strain, can be readily defended Within the last few months I have found it necessary to remove several plasters for skin conditions, and leave them off till they were cleared up I have been surprised in three of these cases to find the incomplete union rapidly become complete, instead of becoming increasingly unstable Possibly others have had a similar experience

Newmarket J GRANT BONNIN

STAPHYLOCOCCAL NURSERY

SIR,—I am prompted by your leading article of Sept 26 to record some hitherto unpublished observations of my own During a 3 months' bacteriological survey of the nursery in a large London hospital I examined nasal swabs from 93 infants between five and seven days old 90 (97%) were carriers of coagulase-positive staphylococci This survey was undertaken during the period of heavy enemy air attacks in the winter of 1941 and the nursery was for this reason situated in the basement of the hospital It was not understaffed or overcrowded but there was no direct ventilation During the period under review there were amongst these 93 infants 22 cases of mild clinical infection, "sticky eyes" and skin lesions of various kinds, attributed to staphylococcal infection, these organisms being recovered in profuse culture from all the lesions examined The staphylococci from the first five "sticky eyes" were examined by Dr E H Gillespie and all were found to belong to Cowan's type 1 No attempt was made to type the staphylococci from the remaining cases As a control to these observations (and through the kindness of Mr Eardley Holland) I took nasal swabs from 32 infants in three emergency maternity homes situated in the country Of these children, who were in a similar age-group to the London children, only 11 (34%) were found to be nasal carriers of coagulase-positive staphylococci In none of these three homes had there been recent outbreaks of staphylococcal infection

The number of children examined in the country homes is admittedly too small for the results to bear statistical analysis, but superficially there appears to be a marked discrepancy between the two groups, town and country It seems possible that the high carrier-rate obtaining in the town group, which is in accord with the observations of other workers in this field, may have been associated with the local conditions under which the infants were living, the degree of dust pollution of the atmosphere and the prevalence of staphylococcal infections in their immediate environment A staphylococcal outbreak certainly appeared to be in progress during the period of the survey

One further observation made during this survey seems worthy of note Swabs were taken from the eyelids of 45 normal infants in the London nursery 25 (56%) yielded coagulase-positive staphylococci in profuse culture In view of this high carrier-rate it seems that, in the absence of more conclusive evidence, the staphylococcal ætiology of "sticky eye" should be accepted with reserve Where serological methods have established the identity of staphylococci from consecutive cases of pemphigus neonatorum[1] there seems less reason for doubting their causal relationship although even then the evidence is not conclusive With the possible exception of the 5 cases mentioned above where type 1 staphylococci were recovered in profuse culture from 5 consecutive eye infections, the serological method of approach does not yet appear to have been applied to the epidemiology of "sticky eye"

London, W 6 S D ELLIOTT

MEDICAL PLANNING

SIR,—Your report on the BMA representative meeting was illuminating It seems hardly credible that the proposals to await the opinions of the men on service could be turned down and that so close a vote on the no income limit should be considered representative of the profession Truly the spirit of totalitarianism seems abroad in the land Certain members urged that the feelings of those who did not agree with group medicine and health centres should be disregarded, and that "one street one doctor" should be the rule This is indeed a portent of our fate under even the semi-state service of the Planning Commission scheme What mandate has the BMA to abolish private practice? Why forestall a hypothetical government-imposed scheme by running our own heads into the noose? At all costs let us preserve our freedom Our patients prefer to see us in our own homes; when they need specialist services they can be referred to a hospital, often by appointment The scheme is un-English and uproots the traditions of medical practice of which the new President speaks so highly

Gloucester Gate, N W 1 RUSSELL STEELE

CONSIDERATE TONSILLECTOMY

SIR,—Mr Gerrie and Dr Ross Mackenzie are entitled to the last word, but I want to ask them one question Do they agree with the ideals they mention, or do they use the word to suggest the unattainable? If the former, their hospital and its system must conform to what they believe to be the best for their little patients or become a picturesque backwater in the medicine of the past If the latter, let them take courage, and they will find that ideals are attainable These are not merely mine, they are developments from great teachers—Mr F J Steward and Sir William Milligan They have therefore stood the test of nearly 50 years and have the support of leaders of thought in our profession—of physicians, especially when they specialise in diseases of the chest, of administrators in the educational and public health services, and of general practitioners old enough to be seeing into the world children whose parents and grandparents they have saved from tonsillectomy without harm To follow these ideals leads one to apply consideration to the indications for as well as to the technique of tonsillectomy It was Mr

---

[1] Elliott, S D, Gillespie, E H and Holland, E Lancet 1941, i, 169

Steward who, when shutting down tonsil and adenoid operations for the winter, once said that one advantage of doing so was that by the spring you had learnt how many of them were unnecessary Children's hospitals seem not to be conducive to the conservation of the subepithelial lymphatic glands, perhaps because those who work in them see their little patients for so short a period of their lives instead of from eight months to eighty years as others do, but anyone incurs a grave responsibility today who, unless the indications are overwhelming, advises the removal of this protective tissue before the child has withstood the increased droplet infection of the first few years of school life

It is sad to relate that Professor Digby, who by his book *Immunity and Health* (1919) did more than anyone to impress this idea upon the profession, has not been heard of since the fall of Hong-Kong

Guy's Hospital T. B LAYTON

CERTIFICATION OF DEATH IN INFANCY

SIR,—I would like to make one or two observations on Dr Miller's conclusions in his article of Sept 5 Under existing conditions in private practice when a doctor is unable to certify a cause of death he has to notify the coroner The latter is merely concerned to know whether the death is due to unnatural causes and will often, dispense with an autopsy if the facts of the case do not lead him to suspect foul play Lay people often regard an inquest as carrying a stigma and the family doctor, out of regard to the family, is tempted to sign the death certificate on the flimsiest data This state of affairs could be improved by increasing the facilities for post-mortems to be done at the practitioner's request by the provision of large well-equipped public mortuaries with a staff of competent pathologists At the same time an attempt should be made by means of intelligent propaganda to overcome the prevalent lay prejudice against the necropsy. Further liaison between clinical pathological services and the practitioner would be an enormous advantage There should be a staff of technicians to visit the sick baby's home for the purpose of taking blood-counts, blood-films, &c at the practitioner's request. The doctor usually has neither the time nor the special experience required Such facilities do exist but are not sufficiently comprehensive, and in many cases the cost is prohibitive These two provisions would add enormously to our knowledge of pædiatrics, because the greater proportion of childhood ailments have to be treated by the private general practitioner who often has to struggle on without the tools of modern medicine

Newcastle-on Tyne SIDNEY WOOLF

INOPERABLE GASTRIC CANCER

SIR,—I was most interested to read Major Raven's review, in your issue of Sept 19, of the results obtained by the treatment of inoperable carcinoma of the stomach by radon seed implantation Out of five cases I have treated by a combination of gastrojejunostomy and radon implantation one case seems worth recording because of the remarkable improvement in general condition and prolongation of life beyond the usual expectancy This patient was 58 years of age, with an inoperable pyloric carcinoma Following the operation considerable improvement in health was apparent, although convalescence was at first somewhat delayed by wound infection He put on nearly a stone in weight after leaving hospital and surprised me three months later by telling me that he had gone back to work When he was seen fourteen months after his operation he was still doing light work and was without symptoms At that time a barium meal showed the same original deformity at the pyloric end of the stomach

Gidea Park. D LANG STEVENSON

ANÆMIA IN PREGNANCY

SIR,—Your leading article (Sept 19, p 337) brings together forcibly the present views of some workers upon the blood condition of antenatal cases While macrocytic anæmias are comparatively rare the microcytic type appears to be increasing both in these women and in the community at large The article suggests that iron in absorbable form should be widely provided but states that the "fortified milk scheme" *would be difficult to carry out* It would however, be possible to fortify the bread (though previous discussions in the *Lancet* and the *British Medical Journal* make me hesitate to suggest any further modification of this essential food!) Fortification with iron phytate, sodium ferric pyrophosphate and ferrum redactum was, however, satisfactorily carried out in the United States before the war, so that the practicability of the method has been established (Council on Foods and Nutrition, *J Amer med Ass* 1941, 116, 2819, *Ibid* 1941, 117 300) There appears to be some disagreement as to the efficacy of the iron compounds then used (Free, A and Bing, F *Nutrition*, 1940, 19, 449, Widdowson, E M *Nature, Lond* 1941, 148, 219, Widdowson, E M and McCance R A *Lancet*, 1942, i, 588), but further experimental work might well provide a more satisfactory form in which to introduce iron into bread Critics may contend that everyone does not require extra iron, but these I would ask whether harm from increased iron intake has ever been proved, while to the large proportion of the population who are now iron deficient the effects would be extremely beneficial

Farnborough, Kent HELEN P. WRIGHT.

PLANNED NUTRITION

SIR —The recent drive for the formation of a Nutrition Council, primarily planned for the benefit of the Ministry of Food, ignores the history of that ministry in its relations to scientific advisers It is clearly futile to establish yet another advisory committee, no doubt with an expensive secretariat, personnel, officers, and so forth unless there is some probability that its advice will be taken by the ministry for whom it is mainly provided The history of the Ministry of Food in this respect gives little encouragement to this expectation Experience of the past three years has in fact demonstrated that multiplication of committees has provided a convenient smoke-screen for ministries, behind which they pursue, undisturbed, policies often having no scientific sanction and principally dictated by the permanent staffs of individual departments

House of Commons E GRAHAM-LITTLE.

ANÆSTHETIC MORTALITY

SIR,—I should like to support Dr Rawdon Smith in stressing the imperative necessity of recording anæsthetic fatalities I am afraid there can be no doubt that we have been grievously misled about the safety of some of the newer anæsthetic agents During the past twenty years I have worked frequently at a number of suburban and provincial hospitals, where most of the anæsthetics are given by general practitioners, who use chloroform freely and openly. In all this time I have never seen a chloroform death and I have never heard of a chloroform death occurring at these hospitals With spinal, intravenous and local anæsthesia, this is not the case There have been in my own district a number of fatalities from these newer anæsthetic agents, not one of which has been reported in the medical press We can only make an actuarial estimation of anæsthetic risks from a study of anæsthetic fatalities, and unless these fatalities are published we are completely at sea

New Barnet. JOHN ELAM

LIAISON

SIR,—While the difficulties in establishing liaison between the Civil Defence, the Home Guard, and the RAMC as outlined by Z M A. are no doubt true for many localities, it would be erroneous for your readers to suppose that they are true universally Here in Ramsgate we have established at least the beginnings of satisfactory cooperation and have held exercises to try out our organisation I will not claim that we have solved many of our problems, but at least we are beginning to see precisely what they are—which is the first essential step towards solving them Your correspondent's difficulty with the Civil Defence authorities, when he was told that there was no order in the civil defence service touching the matter of liaison with the Home Guard, seems inexplicable, for there is in existence a Ministry of Health circular (No 2486) dated Sept 12, 1941 which deals with this matter It is in fact, for a circular reasonably clear and certainly provides the basis upon which a scheme may be built

Ramsgate J V WALKER,
Medical Officer of Health

Obituary

HEDLEY DUNCAN WRIGHT

B A TASMANIA, M D, D SC EDIN, M R C P E

Hedley Wright came to this country from his native Tasmania in 1910, and while still an undergraduate at Edinburgh he went to Serbia as a dresser in the Scottish Red Cross unit during the second Balkan war As soon as he graduated with first-class honours in 1916 he obtained a commission in the RAMC and served in France, India, Baluchistan and Persia before he returned to civilian life in 1920 Wright's career as a bacteriologist was started auspiciously under James Ritchie in his own university and continued, under A G McKendrick, as assistant superintendent of the research laboratory of the Royal College of Physicians of Edinburgh By McKendrick he was initiated into the mysteries of statistical analysis as applied to biological problems, a discipline which was later to stand him in good stead, and he always spoke of that association as one of the happiest and most fruitful in his life But it was as lecturer, and later reader, in bacteriology at University College Hospital medical school under A E Boycott that Wright really began to show his outstanding qualities as a bacteriologist Here he carried out over a number of years his important investigations into the bacteriological and immunological aspects, clinical and experimental, of bacterial endocarditis, pneumococcal septicæmia, puerperal sepsis and other forms of bacteræmia From these studies he was led to a reinvestigation of the subject of nutrient media, with particular reference to the production of an optimum medium for the cultivation of the pneumococcus and related organisms

In 1930 Wright was appointed to the newly instituted chair of bacteriology in the University of Sydney, which he occupied with great distinction With a big new teaching department to organise he had less time for original research, but he was able to continue his studies into the fundamental nutritional requirements of bacteria cultivated in vitro, and he set a fine standard of work for those who were to follow him With his translation to Liverpool in 1934, new fields of inquiry presented themselves, particularly in relation to epidemiology and public health His studies ranged over such practically important subjects as the bacteriology of water-supplies and of pasteurised milk, the laboratory diagnosis of diphtheria, cross-infection in diphtheria wards and the occurrence of diphtheria bacilli in ward dust Most of these studies were made in collaboration with his colleagues Shone, Tucker, Glass and Holt He also made fruitful use of an opportunity which presented itself to investigate an epidemic of paratyphoid fever, and he played a considerable part in the establishment of the Emergency Public Health Service His last contribution, a note of warning as to the possibility of occurrence of diphtheria in inoculated persons, appeared only a month before his death

He was a member of the bacteriological committee of the Medical Research Council and of its subcommittees on cross-infection in hospitals and on diphtheria immunisation He was a fine committee man, wise, blunt in speech, a hard hitter, never allowing himself to be ruffled He also sat on the research advisory committee of the Development Commission and of the University of London committee for making appointments to chairs and readerships in pathology, while in the senate of the University of Liverpool lay members of other faculties listened to his counsel and opinions with more appreciation than those of any other member of the faculty of medicine

Wright has described himself as " a real cricket fan ", and he had played first-class cricket both in Tasmania and in Edinburgh At University College, in later years, he used often to be the far from forlorn hope of his sid in the staff *v* students' match

During 1928–30 and again from 1937 until his deat he had been an assistant editor of the *Journal of Pathology and Bacteriology* and Prof Matthew Stewart, to whom we are indebted for much of the material for this memoir writes " He was an ideal editorial colleague, expeditious business-like and constructively critical His own writings were models of lucidity, and many are gratefu for the help he gave them in the preparation of their papers for the press An upright and fearless man Wright was a fighter where he considered fi necessary, and an indefatigable worker Scholarly thoughtful and philosophical, he had read widely many branches of literature and he was a charmin companion and good conversationalist He had achieve much in his all too short life and he had made many friends by whom he will be remembered as one of truest and best "

Wright's end was clouded by tragedy He had had major operation in January, 1939, from which he made good recovery, but towards the end of last year he bega to go downhill A second operation early this year ga him relief, but did not bring the hoped-for in his general state During the summer term he on going down to his laboratory to give his usual lectures though this greatly exhausted him, and his deteriorated rapidly In July his wife, whose health ha already given cause for anxiety, had a stroke of whic she died a fortnight later And after weeks of physical distress borne with heroic fortitude Wrigh himself died on Sept 9 Of their three sons the el has just taken his degree in chemistry at Liverpool, th second is serving in the Merchant Navy and the third the Royal Navy

ROBERT CECIL ROBERTSON

M C, M D GLASG, F R F P S, M R C P E, D P H

THE news of Cecil Robertson's death at Hong-Kc on Aug 4 will come as a shock to his friends in th country Robertson was not only a brilliant bacterio gist, but he was a born artist With no instruction, save a few hints from his gifted wife, he painted pictures which were accepted by the Royal Academy His wa a robust personality, capable and versatile As soon he saw that a thing wanted doing he set to work did it His organising power was remarkable and leadership inspiring It was my good fortune to be of his colleagues in the Henry Lester Institute of Medical Research, Shanghai, and I well remember his coming to my department and saying, " Here is the Yangtze out of hand, one of the greatest floods in history, what are we going to do about it ? " At once he took the lead One of the Moller line steamers was chartered, partitions torn out, staircases put in and an oldish cargo boat transformed into a hospital ship

Inspired by his drive and leadership, various Chinese and foreign members of the staff of the institute offered their services and within a matter of days he was on his way up the Yangtze to Hankow, combining an errand of mercy with a full-scale investigation of th ætiology and treatment of the diseases which develop side by side with flood conditions

Most of Robertson's colleagues in the Henry Lester Institute were, of course, Chinese, and his devotion to them drew out a like devotion on their part to him, so that he developed a splendid team spirit in his division One day in Shanghai he was taking a small Chinese boy, the son of one of his servants, in his car to have an inoculation when it was seized by armed gangsters His chauffeur was bundled out and the car driven along one of the unfrequented roads on the outskirts of the settlement Robertson realised that he and the boy were being kidnapped Wrapping his great coat round the frightened Chinese boy and holding him snugly to himself, he quietly opened the door and rolled out Before the miscreants could recover from their surprise he had picked up the boy and disappeared among the bushes, making his way to safety

It was no cause for wonder to us who knew him that in August 1937, when Shanghai became involved in the Sino-Japanese war, Robertson at once offered his services to the municipal health department and organised a large part of its relief and refugee work, using the opportunity to investigate deficiency diseases. Or that in 1939, when the League of Nations wanted a commissioner to take charge of the British anti-epidemic unit in China, they invited Robertson to take the lead. With his team of workers he made a splendid epidemiological survey of Southern and Western Yunnan.

To Robertson the need of the sick and suffering was always a call along two lines—to bring relief and to investigate the cause so as to prevent a recurrence. And now he has gone from us and the world is poorer for his passing. To his wife and daughter, who escaped from Shanghai just before the invasion, we tender our respectful sympathy.

H G T

Robertson, who was 52 years of age, graduated from the University of Glasgow in 1911, and for his service with the RAMC during the last war was awarded the MC. On his return he continued for a time to work in the vaccine department of the RAM college, before becoming assistant bacteriologist to the corporations of Bradford and Glasgow in turn. Later he was pathologist to the Ministry of Pensions Hospital at Bellahouston. Much of his work in China was done at the Lester Institute at Shanghai, and it was only in 1940 that he took up his chair in Hong-Kong.

HEINZ LOTHAR MEYERHOF

MD MILAN

Dr Heinz Meyerhof died suddenly at Sherbrooke, Canada, at the early age of 27. Born in Berlin, he spent his youth there and began his medical studies in the university, but he left Germany in 1933 to continue his studies in Milan, where he graduated in 1938 with first-class honours in medicine and surgery. In Italy he supported himself entirely by means of commercial drawings. He undertook research work on the chemotherapy of spirochætosis in the Serological Institute at Milan, and later collaborated with Professor Zirconi in an investigation on the action of embryonic extracts on the sex organs. This work was published in the *Journal of Physiology* in 1940, and was followed by a short paper by Meyerhof himself on lymphocytosis induced by extracts from lymph nodes, a subject on which his MD thesis had been based.

Early in 1939 Meyerhof was forced to leave Italy, and he came to England to continue his investigations in the Department of Pathology in Cambridge, working with a grant from the Society for the Protection of Science and Learning. He was classified by a Home Office Tribunal in October, 1939, as a "refugee from Nazi oppression." In May, 1940, he was interned, being an alien resident in a protected area, but was released in January 1941, and went to Canada where his lectures in medicine and bacteriology were greatly appreciated. His sudden death ended a promising life. Meyerhof possessed a strong artistic vein; and those with whom he came into contact will remember him for the courage with which he cheerfully overcame the many difficulties encountered in his career and for his goodness of heart and happy comradeship.

First Aid Diagrams.—Messrs Adam Rouilly & Co have produced two new wall charts for first aid instruction. One, roughly a yard square, shows 12 fractures, the other, about half that size, shows 4 dislocations. The original drawings are by W J Pardoe, made under the supervision of Professor Smout of Birmingham. The drawings are semi diagrammatic, and contain no needless detail to confuse the student. They are, however, sufficiently pictorial to make the nature of the injuries clear to the back benches and somewhat exaggerated colour is used with effect.

Nutrition Society.—A whole day conference of this society will be held at the London School of Hygiene, Keppel Street, London, W C 1, on Saturday, Oct 17, at 11 AM, to discuss trace elements in relation to health. The chair will be taken at the morning session by Mr J Russell Greig, PH D, and at the afternoon session by Prof C R Harington. Further details from the hon secretary, Mr Leslie Harris, D SC, Dunn Nutritional Laboratory, Cambridge.

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Notes and News

MINIATURE MASS RADIOGRAPHY

At a meeting of the Joint Tuberculosis Council held on Sept 19 Dr G. Jessel presented a careful report by the radiology committee which was adopted. During the discussion emphasis was laid by Dr R A Young on the necessity for regarding X-ray examination as an integral part of medical examination as a whole; it was most undesirable that one negative radiogram should be regarded as proof of immunity from tuberculosis for all time. The council thought it impossible as yet to estimate with any degree of accuracy the number of beds which should be available for new cases discovered by mass investigation. There was some difference of opinion about who should interpret the small films, one of a panel of clinicians or a radiographer. Common ground was found in all the following propositions. Mass radiography should be treated as part of a general health survey and not related in the public mind specifically with tuberculosis. It would neither be desirable nor generally possible for mass radiography to be carried out at existing tuberculosis dispensaries, but tuberculosis officers should take an active part in reading the films and investigating the suspects. A central committee approved by the Ministry of Health with a medical advisor should be established to coordinate and supervise mass radiography. Sets should be lent to selected county and county borough councils after an approved scheme has been submitted by the medical officer of health and tuberculosis officer. They should be set up in centres convenient to large numbers of workpeople and moved to other premises from time to time for the examination of further batches. Groups for examination might include (1) Government and local government staffs, civil defence personnel, post office employees, police, fire brigade, and so on; (2) Workers in munition works and other industries, particularly those known to provide an undue proportion of cases of tuberculosis; (3) Secondary school leavers. Special attention should be given to age-groups 16–30 years. The staff employed in mass radiography should receive some central training. The small films would be read by one of a panel of clinicians, including the local tuberculosis officer and radiologist. Suspicious films should lead to a full-size radiogram being taken. This, if suspicious, would in turn lead to a full investigation at the local tuberculosis dispensary or general hospital. Permission was given by the Council for the report to be used for propaganda purposes in the scheme about to be launched.

THE FRENCH AND BELGIAN WAY

The Belgian review *Message* is still a young journal not yet out of its first year. Among English and French articles of general interest, the August issue contains an account[1] of the Centre de Rééducation at Finedon, Northants, where men leaving the Services are refitted to earn their livelihoods. The centre is sponsored and largely financed by General de Gaulle, but it is helped too by other friends and by numerous gifts and subscriptions. It differs strikingly from its English counterparts in being run jointly by an artist and a scientist. Joseph Lacasse, the artist, is a Belgian; Colonel Baranger is French. They are old friends and have worked together in France before the war, to provide work and opportunities for struggling artists. At Finedon Hall something of the freedom of an atelier has been created even on our unpromising British soil. Newcomers are not pressed to take up any special form of work; they wander round and see what is being done, try their hand at this or that, and gradually become absorbed by some art or trade, until they are working hard at it from choice. Thus a man who began as a carpenter is now one of the most promising artists in Lacasse's studio. Craftsmen can take up their old trades or try new ones. The care of the house is in the hands of the residents: they began by piping their own water-supply; they replace crumbling stone and are providing a summer room with window frames and glass against the English winter. Bricklayers and carpenters thus find work ready to their hand; blacksmiths and metal workers can use the forge, potters and shoemakers find the materials of their craft waiting for them, a printing press is being installed, and fabrics are woven In the Victorian-Gothic tower Colonel Baranger and his assistants have their laboratories, and some patients discover a liking for work at the bench or undertake care of the animals Dress is according to taste, and everyone smokes anywhere he pleases This wholesome lack of useless restrictions is something of a lesion for us, who still lurk in a cocoon of red tape

---

LCC AND PREMEDICAL STUDY

The Interdepartmental Committee on Medical Schools have asked the London County Council for their views on medical education The only aspects of the subject which the council think directly concern them as a local education authority are the facilities available for medical students in their preregistration period and the scholarships and exhibitions which can be given to students who need help The council are of the opinion that the proper place for the study of the preregistration subjects is the secondary school and not the medical school and that their study should be increased The county scholarships and exhibitions are not limited in number and all students who secure the required academic qualification are eligible The scholarships are tenable in London or in the Provinces, but there is evidence that London students, both men and women, are finding it difficult owing to the increased number of applications to obtain admission to medical schools in London The council further state that any arrangements which they might make to further medical education would, of course, be open equally to both men and women, and they would expect to be treated financially by the Government not less favourably than the voluntary teaching hospitals and medical schools.

London Voluntary Hospitals

The 162 voluntary hospitals within metropolitan London have now 22,400 beds, where during 1941 over 1,300,000 patients were treated at a cost of over £4 million These figures include the 1,214,000 outpatients who made over 5,500,000 attendances at the hospitals The 39th annual statistical report of King Edward's Hospitals Fund for London, which has just been published, shows also that there were ample funds to meet the expenses of this service Income was £4,299,000, or £216,485 more than was needed to balance the maintenance budget In addition, £429,376 was received as free legacies, which brought the surplus up to £654 821 The report is limited to the hospitals operating within the metropolitan police area, and takes no account of beds provided and staffed by London voluntary hospitals outside this area under the Emergency Medical Service

Royal Society of Medicine

During the coming week four presidential addresses will be given at this society On Tuesday, Oct 13, at 2 30 PM, at the section of psychiatry, Dr John Brander will speak on medical and social implications of psychological medicine, on Oct 14, at 4 30 PM, at the section of physical medicine, Dr Philippe Bauwens will speak on physical medicine and planning for the future, on Oct 15 at 4 30 PM, at the section of neurology, Dr R Mackenzie Stewart will speak on the pathology of cerebral diplegia, and on Oct 16, at 4 PM, at the section of radiology Dr F M Allchin will speak on radiography as the handmaiden of radiotherapy On Oct 16, at 3 30 PM, the section of obstetrics and gynæcology will also meet, when Prof Dugald Baird and Prof Charles McNeil will open a discussion on stillbirth and neonatal mortality

Faculty of Radiologists

A meeting of the therapy section of the faculty will be held at 10 AM, on Saturday, Oct 17, at 32, Welbeck Street, London, W 1, when Dr F Ellis, Mr C W Wilson and Dr J L Dobbie will open a discussion on beam direction in radiotherapy

Association of Scientific Workers

On Sunday, Oct 18, this association will hold a conference at Cardiff on science for victory Speakers will include Dr F H Tyrer and Dr J Greenwood Wilson Further information may be had from the Conference Secretary, 130, Cardiff Road, Llandaff, Glam

Infectious Disease in England and Wales

WEEK ENDED SEPT 26

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1963, whooping-cough, 938, diphtheria, 807, paratyphoid, 13, typhoid, 9, measles (excluding rubella), 3356, pneumonia (primary or influenzal), 459, puerperal pyrexia, 161, cerebrospinal fever, 70, polio myelitis, 32, polio-encephalitis, 7; encephalitis lethargica, 2, dysentery, 237, ophthalmia neonatorum, 112 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Sept 23 was 1497, including scarlet fever, 415, diphtheria, 177, measles, 172, whooping cough, 218, enteritis, 71, chicken-pox, 49, erysipelas, 37, mumps, 42, poliomyelitis, 7, dysentery, 29, cerebrospinal fever, 5, puerperal sepsis, 26, enteric fever, 12, german measles, 1, continued fever 6, other diseases (non-infectious), 125, not yet diagnosed, 95

Deaths —In 126 great towns there were no deaths from scarlet fever or the enteric fevers, 2 (0) from measles, 13 (2) from whooping-cough, 21 (0) from diphtheria, 70 (10) from diarrhœa and enteritis under two years, and 6 (0) *from influenza The figures in parentheses are* those for London itself

Manchester reported 8 deaths from diarrhœa, Liverpool 7, no other great town more than 3

The number of stillbirths notified during the week was 223 (corresponding to a rate of 36 per thousand total births), including 23 in London

Births, Marriages and Deaths

BIRTHS

Bell Tawse —On Sept 28, at Southborough, the wife of Dr Alan Bell Tawse, RAFVR—a daughter

Chapman —On Sept 30, at Edenbridge, the wife of Surgeon Commander W Rougier Chapman, RNVR—a daughter

Crisp —On Sept 29, at Chorley, the wife of Captain W J C Crisp, FRCS, RAMC—a son

Edward —On Sept 28, at Cardiff, the wife of Dr D G ff Edward—a son

Hambly —On Sept 28, at Seer Green, Bucks, to Dr Elizabeth Hambly (née Cadbury), the wife of Mr Edmund Hambly, FRCS—a son

Lock —On Sept 25, at Guildford, the wife of Surgeon Lieutenant J A N Lock, RNVR—a son

Pollard —On Sept 26, in Oxford, the wife of Captain Graham Pollard RAMC—a son

Wheatley-Levitt —On Sept 27, in Aberdeen, the wife of Surgeon Lieutenant C Wheatley-Levitt, RNVR—a daughter

Wise —On Sept 26, at Adlington Hall, Cheshire, the wife of Lieutenant Lionel Wise, RAMC—a daughter

MARRIAGES

Caldwell—Deakin —On Sept 29 at Ewell, Surrey, David Laurie Caldwell, MRCP, to Ann Gilian Deakin

Hickinbotham—Cadbury —On Sept 26, at Birmingham, Paul Frederick John Hickinbotham, FRCS, lieutenant RAMC, to Catherine Rachel Cadbury

Lambert—Pledger —On Sept 26 at Easthampstead John Lambert MD, of Wellington College, to Vera V Pledger, of Peterborough

Pinniger—Pratt —On Sept 8, at Hoyland Yorks, John Lawrence *Pinniger* MRCP *to Katharine Mary Pratt*

Schott—Loewi —On Sept 28, in London, Adolf Schott, MD, of Harley Street, to Erica Loewi

DEATHS

Andrew —On Sept 27, at Hendon, Francis William Andrew, MRCS, aged 75

Bateman —On Sept 25, at Bexhill on Sea, Charles Edward Gooderson Bateman, LRCPF, aged 79

Carr —On Sept 29, John Walter Carr, CBE, MD LOND, FRCP, FRCS, aged 80

Diggle —On Sept 30, at Dunham Massey, Cheshire, Frank Holt Diggle, OBF, MB MANC, FRCS

Ewart —On Oct 2, at Weybridge, George Arthur Ewart, BA CAMB, FRCS, aged 56

George —On Sept 26, at Paignton, Richard Julyan George, MD EDIN, DPH

Kidd —On Oct 2, Leonard Kidd, MD DUBL, DL, of Enniskillen, aged 79

Moore —On Sept 27, at Cheltenham, Robert Reginald Heber Moore, CBE, MD DUBL, late colonel RAMC, aged 83

Peck —On Sept 27, at Bourne End, Bucks, Eric Finch Peck, MRCS

Robertson —On Aug 4, in Hong-Kong, Robert Cecil Robertso MC, MD GLASG, FRFPS, MRCPE, D PH, professor of bacteriology pathology, aged 52

FATE OF TRANSFUSED PLASMA *

JOHN BEATTIE, M.D., D.SC. BELF.

BERNHARD BARON RESEARCH PROFESSOR AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

Two and a half years ago, the first samples of citrated plasma for transfusion arrived with the BEF in France. They had been prepared by Whitby and his colleagues who had developed a successful technique for the production of plasma in bulk and whose pioneer work was largely responsible for the adoption of plasma-transfusions as a routine in the treatment of casualties.

After severe hæmorrhage or extensive trauma, one of the most important principles in treatment is to restore the blood-volume. Isotonic fluids containing no plasma proteins produce but transient beneficial effects, while plasma-transfusions raise and sustain the blood-volume. Responses to plasma-transfusions, however, are unfortunately variable, even when clinical or experimental conditions are apparently identical. Observations of changes in hæmoglobin and plasma-protein concentrations show that such changes are due to at least five factors: (1) the simple mixing of transfused plasma with the circulating blood; (2) the formation of a surface film of plasma on the walls of the expanded vascular bed; (3) the establishment of colloidal osmotic equilibrium between the plasma of the axial stream and that of the peripheral film of plasma; (4) the migration of fluid either into or out of the blood; (5) the translocation of plasma protein from or into the blood. It is by the interplay of these factors that the hæmoglobin and plasma-protein concentrations and the total blood-volume are finally determined.

* * *

In man it has been shown (Ebert and Stead 1941) that there is no evidence of a store of red cells which can be discharged into the blood-stream to increase the total amount of circulating hæmoglobin. Consequently changes in hæmoglobin concentration are due (in man) to variations in the quantity of circulating plasma. It is important to realise at once that blood samples give an indication of the proportion of hæmoglobin in the *actively circulating* blood, for this does not constitute the whole of the blood-volume. Plasma exists in the blood-stream as two components, one acting as a fluid matrix for the cellular elements and the other forming a fluid lining for the blood-vessels. In a normal person, about 79% of the total plasma-volume behaves as the cell matrix, the remaining 21% as the peripheral film on the vessels. Since the thickness of the film increases as the velocity of the axial blood-stream diminishes, the greatest thickness is to be found in the capillaries. These vessels possess by far the greater part of the surface area of the whole vascular bed, so that the greater part of the peripheral film component of the plasma-volume is to be found in the capillaries (Hahn et al. 1942).

When plasma is added to the blood-stream it mixes with the axial blood, and simultaneously the vascular bed expands to accommodate the increased blood-volume. If this expansion is effected by an increase in the diameter of the existing vessels, the amount of plasma required to form a film over the increased surface area would be small relative to the increase in volume, and hence the fall in hæmoglobin concentration would be maximal. If however the expansion is effected more by the opening up of capillaries previously closed, then provided no fluid moves out of the blood-stream, much of the added plasma would form a surface film on these "new" capillaries. The amount of plasma available for dilution of the axial blood-stream would thus be reduced, and the fall in hæmoglobin concentration would be minimal.

Differing methods of expanding the vascular bed, then, may account for some of the discrepancies between the expected and observed values for hæmoglobin concentrations after plasma-transfusion; but another factor may be operating. Fluid shifts into and out of the blood-stream rapidly in cats and less rapidly in dogs and human subjects. If much fluid shifts out of the blood-stream after a plasma-transfusion, the fall in hæmoglobin concentration due to the transfusion is much less than that expected. Sharpey-Schafer and Wallace (1942) showed that the injection of large quantities (up to 1700 c.cm.) of normal serum produced in some normal subjects only a small and transient fall in hæmoglobin concentration (within 10 minutes). If these subjects responded to an increased blood-volume by opening up "new" capillaries, the speed with which fluid could leave the circulation would be increased, because of the increased surface area of capillary wall available for fluid to leave the blood-stream. Other subjects in the series showed falls in hæmoglobin concentration of the order of 20%, and required days to regain their pretransfusion level of hæmoglobin—and presumably their normal blood-volume. If these accommodated a large part of the transfused serum in their larger vessels—presumably veins—the loss of excess fluid would be much slower than in the first group.

If it be assumed that no red cells are added to the circulation during the period of observation—and in man this assumption is almost certainly true—then the ratio of hæmoglobin after transfusion to that before transfusion would be equal to the ratio of the blood-volume before transfusion to the blood-volume before transfusion plus the fluid transfused, provided that all the fluid transfused remained in the circulation and that all of this fluid was used to dilute the circulating blood. Since it appears certain that fluid leaves the circulation, and also that some part of the transfused plasma is required to form a surface film on the expanded vascular bed, then, if these two ratios are equated, the greater the loss of fluid from the circulation or the greater the proportion of the transfused fluid immobilised as a surface film, the greater will be the calculated blood-volume.

Hayward (1942) transfused with known quantities of serum 8 subjects all suffering from peripheral vascular disease of a sclerotic type. He observed the fall in hæmoglobin concentration immediately after the end of transfusion. When blood-volumes are calculated from these figures, 4 out of the 8 subjects showed values in excess of the normal value. These high values were 10·29, 7·35, 6·8, and 5·7 litres. As the time taken to give the transfusions of 800 c.cm. varied between 1 and 3 hours (at the rate of 5–15 c.cm. per min.), fluid loss from the circulation must have been considerable, although Hayward stated that "after an initial increase equal to the amount of serum injected, the blood-volume gradually returns to normal over a period of from 2 to 3 days." Since these subjects had abnormal vessels, it is not improbable that the immobilisation of some of the transfused serum on the walls of opened-up capillaries might account partly for the small fall in hæmoglobin concentration.

These results were obtained in subjects who had not suffered any loss of blood. Kekwick and his colleagues (1941) made a study of the effects of plasma-transfusions on subjects who had been injured in air-raids. In one of their cases a loss of 1000 c.cm. of blood had been estimated. After transfusion of 2 pints (1126 c.cm.) of citrated plasma, the hæmoglobin concentration fell from 110% to 85%. If it be assumed that all the plasma transfused mixed with the axial blood-stream and that none was lost as a surface film or from the circulation, the calculated blood-volume of this patient would have been 3829 c.cm. before transfusion. This is not an unreasonable figure and would suggest that either little fluid had left the blood-stream or little plasma had been used to form new surface films, or both these had occurred simultaneously. If however—as is almost certain—some fluid had left the blood-stream during the transfusion, it would not be unreasonable to assume that the loss would not exceed the volume (300 c.cm.) of diluting citrate solution added to the plasma. The volume of fluid left to dilute the axial stream would be about 825 c.cm. The blood-volume calculated on this basis before transfusion would have been 2805 c.cm., or a difference from the previous calculation of 1 litre.

Again some of the transfused plasma must have been used to form a surface film on the expanded blood-vessels. This would still further reduce the calculated blood-volume, but by what amount cannot be estimated. Kekwick's estimate of the loss of blood in this patient was probably conservative and a loss of 2 litres would have been more likely.

---

* Based on two Bernhard Baron lectures given at the Royal College of Surgeons of England on June 2 and 10, 1942.

Assuming that after the hæmorrhage but before transfusion the blood-volume was 3 litres, and that the increase in blood-volume after 2 pints of plasma was about 825 c cm , the approximate blood-volume before a third pint of plasma was given would be 3825 c cm The hæmoglobin concentration fell from 85% to 80% after the transfusion of the third pint This would give a calculated blood-volume of 9008 c.cm , assuming that there was no fluid loss and all the plasma transfused diluted the axial stream Obviously, therefore, a considerable proportion of this third pint was lost from the axial stream either by being immobilised as a surface film on expanded vessels or by leaving the circulation If we assume that the actual blood-volume was 3825 c cm before the third pint of plasma was given, only 239 c cm of fluid would be required to provide the necessary blood dilution Thus, of this third pint (563 c cm), about 324 c cm was "lost" Since the plasma equivalent of this pint was about 413 c cm , only 150 c cm of this loss could be accounted for by the removal of the protein-free diluting fluid from the blood-stream It is therefore clear that after hæmorrhage considerable fluid loss from the circulation can take place, even when the blood-volume is still below the normal level, and at the same time there is a considerable opening up of closed capillaries

These deductions are at best indirect evidence that the capillary field opens up when the blood-volume is increased Since they are based on observed values which are themselves liable to considerable error (± 2% for hæmoglobin determinations), the calculated values for blood-volumes would be valueless were it not for the fact that three different observers have noted in man considerable discrepancies between the observed and expected values for hæmoglobin concentrations, and moreover these discrepancies were of the same sign the observed values were higher than the expected ones The same discrepancies have been noted in anæsthetised animals (Beattie 1942)

When plasma or serum is transfused into normal human subjects or experimental animals, the pre-transfusion blood-volume is restored, rapidly in some subjects, less rapidly in others Again, transfusion of plasma, with normal plasma-protein concentration, into human subjects or animals which have suffered severe hæmorrhage does not necessarily restore the blood-volume to the normal value, even when the quantity of plasma transfused is equal to or considerably exceeds the total volume of blood lost Our knowledge of the mechanisms involved in the control of blood-volume within normal limits are as yet incomplete

* * *

The plasma-protein concentration in the axial stream after a transfusion is determined by many factors If a rapid transfusion is given of plasma containing a concentration of plasma protein considerably less than that of the animal's own plasma, many animals show, about 10 min after the end of transfusion, a concentration of plasma protein in the axial stream much in excess of their plasma before transfusion This sudden excess of plasma protein cannot be accounted for by a sudden outflow of fluid from the blood-stream It seems, on the contrary, that it is due to an actual flow of plasma proteins into the circulating blood-plasma (Beattie and Collard 1942b) The stimulus to this outflow of plasma protein may be the low plasma-protein concentration in the transfused plasma , but if this is the adequate stimulus, it is not adequate in every animal , some other factor must be involved

After this preliminary rise in protein concentration in the plasma, there is a decline during the first 30 min , which may be due to diffusion into the peripheral plasma film of some of the protein tending to bring this film into osmotic equilibrium with the plasma in the axial stream Such a fall may be due also to an active removal of plasma proteins from the blood Since the fall takes place without any evidence of a change in plasma-volume or hæmoglobin concentration, it is apparently not due to an outward movement of fluid from the blood

There is now ample evidence that plasma proteins can enter the blood rapidly after hæmorrhage, to maintain a constant plasma-protein concentration in spite of the entry of fluid into the blood-stream (Wallace and Sharpey-Schafer 1941) Likewise, it has been shown in normal human subjects that the introduction of large quantities of plasma or serum into the circulation may be followed by little or no significant change either in hæmoglobin or plasma-protein concentration (Sharpey-Schafer and Wallace 1942) This can only be interpreted as a simultaneous movement of fluid and plasma protein from the circulation Similar observations have been made in experimental animals (Beattie 1942, Beattie and Collard 1942a) In man the rate of this inflow of protein to the blood may be estimated from 2 subjects included in Wallace and Sharpey-Schafer's data (1941)

Subject 19 was bled 750 c cm of blood , 4 hours later he reached his state of maximum hæmoglobin dilution, which may be regarded as the attainment of a prehæmorrhage blood volume The plasma protein concentration at this time was 6 9 g per 100 c cm , hence the total plasma protein added was at least 51 75 g , or a rate of addition equal to about 13 g per hour Assuming a body-weight of 65 kg , this would be an addition of 0 2 g per kg of body weight per hour In this subject it was determined directly that the blood-volume had been fully restored at the time of maximum dilution Subject 21 was bled 720 c cm , 19 hours later he reached maximum dilution and his blood-volume then had increased from 5·3 l before hæmorrhage to 6 6 l after hæmorrhage The plasma protein concentration before hæmorrhage was 7 8 g per 100 c cm , and at maximum dilution it was 6 8 g per 100 c cm The total plasma protein in circulation before hæmorrhage was 413 4 g , at maximum dilution it was 448 8 g , representing a gain of 35 4 g But all the plasma proteins lost by hæmorrhage were also replaced The quantity of plasma protein lost may be estimated at 54 g (taking the average concentration of the plasma as 7 5 g per 100 c cm) The total replacement in this subject was, therefore, about 89 g , distributed over 19 hours, or 4 7 g per hour With a body weight of 65 kg , the rate of replacement would be approximately 0 07 g per kg of body weight per hour. The rate of replacement is probably not uniform, and these estimates may not represent with any accuracy the rate during the early phases of replacement

The rate of removal of plasma proteins may be estimated *in 2 subjects included in the series of* Sharpey-Schafer and Wallace (1942)

These showed no change in hæmoglobin concentration when one, subject 1, received a transfusion of 1000 c cm of normal serum over a period of 13 min , and the other, subject 14, received 300 c cm of serum concentrated to four times normal strength In subject 1 no values are given for the plasma protein concentration but it can be assumed from other statements in the article that he showed no significant change in plasma protein after the injection Since the range of plasma-protein concentrations for the serum injection was from 6 to 8 g per 100 c cm , the total amount of protein leaving the blood stream was of the order of 60–80 g in 13 min , or 4 6–6 1 g per min (a rate of 276–366 g per hour) Subject 14 removed somewhere between 76 8 and 100 2 g of protein within 12 min The small rise in concentration recorded (7 2 to 7 3 g per 100 c cm) is probably of no significance The rate of removal in this subject was of the order of 6 4 –8 4 g per min , or 384–504 g per hour

There is abundant evidence that the removal of such quantities of plasma protein from the circulation, whether in human subjects or animals, is not accompanied by any significant increase in nitrogen output The conclusion that the protein is removed into a store or stores of some kind seems the probable explanation , Whipple (1940) has provided evidence that such storehouses do exist in animals When considerable quantities of plasma-protein are given by repeated transfusions to animals (Beattie and Collard 1942b), at first there is a tendency for the plasma-protein concentration, after some variation within 30 min of the transfusion, to become stabilised at or about the pretransfusion level With further transfusions, eventually a stage is reached when the plasma-protein concentration is elevated and remains elevated for some hours This may be regarded as a sign that the storehouses have been filled and that excess plasma proteins can only be retained by expanding the blood-volume or increasing the plasma-protein concentration, or by both measures

It has been suggested that the liver is an important, if not the most important, storehouse Taking the rate of removal in man to be of the order of 7 5 g per min and the average weight of the liver to be 1500 g , the liver would require to store protein at the rate of 0 5 g of protein per 100 g. of liver per min. Since the rate of blood-flow in the liver is about 150 c.cm. per min. this would mean a removal of 0·3 g. of protein from every 100 c.cm. of blood, or from about 50 c.cm. of plasma per min. over a period of 12–13 min. This rate of removal seems too high to be within the capacity of the liver alone.

There is evidence that protein can be removed from the circulation by hepatectomised animals in quantities which suggest that stores exist elsewhere than in the liver, but these results cannot yet be compared directly with the human data of Sharpey-Schafer and Wallace (Beattie and Collard 1942b). The site of these alternative stores has not been determined. It may well be that each living cell can act as a protein store. If we accept Whipple's hypothesis (1940) that the plasma proteins and the dispensable proteins of the body cells form parts of a single protein system in dynamic equilibrium, then we can visualise the plasma proteins as being one reservoir and the dispensable proteins of the body cells as another. Using this reservoir analogy, a fall in plasma proteins in the blood would tend to be compensated for by a flow of protein into the blood, as happens after hæmorrhage. When plasma-protein concentration increases as fluid leaves the blood-stream, protein moves out of the blood into the stores until equilibrium is established. This process could continue until the capacity of the body cells to hold excess protein was exhausted. Rises in plasma-protein concentration after repeated plasma or serum transfusions may thus be the first sign of protein intoxication. Though the liver is probably not the only storehouse of protein, it is undoubtedly the site of manufacture of plasma protein. Plasma protein is not only in a sense a store of protein, it is also the gold standard of protein exchange—an essential part of Whipple's dynamic equilibrium of protein.

The increase in protein reserves which plasma-transfusions bring about may be almost as important as the increase in blood-volume which follow them. The drain on these reserves in severe infections and after extensive burns is obviously great; to support them may be as valuable as to combat bacterial invasion by sulphonamides. In shock, for some reason as yet unknown, the rate of plasma-protein replacement is slow, but as the plasma-volume is increased the rate of replacement also increases (Ebert et al. 1942).

This is not the place to discuss how the dispensable proteins of the liver or body cells are mobilised and transferred so rapidly to the blood, or how plasma proteins can leave the blood-stream even more rapidly. Movement of fluid into the blood-stream takes place at rates, in man, of the order of 200 c.cm. per hour. At the same time plasma proteins can enter at rates of about 15 g. per hour. Such rates of movement are but average rates, and soon after hæmorrhage may conceivably be much higher. On the other hand, after transfusion fluid may leave the blood-stream at rates of 100 c.cm. per *minute* and plasma proteins at rates of 4–6 g. per min. It is by no means clear how these massive movements are effected without ill results.

This study of the fate of plasma-transfusions shows clearly that we have yet much to learn of the mechanisms involved in the control of plasma-volume and mass movements of plasma protein. A more complete understanding of these may enable us to answer the question "What do we mean by shock?" and to treat more effectively the conditions included under that name.

I wish to thank Miss H. B. Collard for her collaboration, Dr. R. B. Fisher for his criticism and the statistical treatment of some of our results, the Rockefeller Foundation for their assistance in providing temporary laboratories when our own were damaged by enemy action, and the President and Council of the College for their constant encouragement.

PERIPHERAL VASONEUROPATHY AFTER CHILLING

"IMMERSION FOOT AND IMMERSION HAND"*

C. C. UNGLEY, M.D. DURH., F.R.C.P.
SURGEON COMMANDER R.N.V.R. IN A NAVAL HOSPITAL

Notes on the MORBID ANATOMY

WILLIAM BLACKWOOD, M.B. EDIN., F.R.C.S.E.
PATHOLOGIST, SCOTTISH MENTAL HOSPITALS LABORATORY, ROYAL INFIRMARY, EDINBURGH

IMMERSION foot, as seen in this war in men who have been exposed in rafts and open boats with their legs immersed in cold sea water, closely resembles the condition called trench foot in the last war. The hands may be similarly affected. The following account is based on upwards of 80 cases seen in Scotland in the last 2½ years.

CLINICAL FEATURES

During exposure, which lasted for periods up to 14 days, the immersed limbs soon became numb; the hands felt clumsy, and some patients described walking "as if on cotton-wool." Pain, tingling and even itching were unusual; cramps sometimes occurred, usually in the calves. Swelling of bare feet was noticed after some hours or days, or otherwise not until the boots felt tight. The skin, red at first, was later pale, "sickly yellow," mottled, blue or black; at sea-freezing temperatures it might remain vivid red. The symptoms and signs observed in the affected limbs after rescue may be described in three stages.

1. *The prehyperæmic stage* lasts from a few hours to several days. The extremities remain cold, somewhat swollen, discoloured and numb, with fairly extensive glove or sock anæsthesia. Peripheral arteries may be pulseless for some hours, and remain so in cases going on to gangrene.

2. *A hyperæmic stage* follows, and may last 6–10 weeks. Typical findings in this stage are:

(*a*) *Vascular disturbances.*—The skin of affected parts remains hot and red at a temperature of 30–34° C., even when the unclothed body is exposed in a cool room; the usual temperature gradients are absent, digits being as hot or hotter than the groins or axillæ. The affected parts, red with a slight bluish tint, become congested on hanging down to a deep purplish red and blanch rapidly when elevated. Blanching from finger pressure disappears quickly except in parts destined to become gangrenous. Such parts are not warm like the rest of the limb; a line of demarcation forms later.

(*b*) *Swelling* often increases, especially if the extremities have been warmed; it pits on pressure, except in the digits or where there are hæmorrhages. With rest it subsides within 3 or 4 weeks.

(*c*) *Sensory disturbances.*—Tingling (pins and needles) is felt early, may increase at 7–10 days, and often lasts 6 weeks; of glove or sock distribution, it is increased by hanging or warmth. Affected parts ache or throb; shooting pains, often delayed until 7–10 days, occur as sharp stabs, frequently several at a time, at irregular intervals. Worse at night and often calling for morphia, the pains are made worse by warmth; they sometimes begin after the first hot bath. The feet may be thrust outside the bedclothes. Pains tend to be more noticeable when the feet are dependent, during and after exercise, after exposure to cold, sometimes during micturition and defæcation, and occasionally with coughing or yawning.

Sensory loss may have shrunk, but retains its glove, sock or slipper distribution; upper levels are often ill defined. Anæsthesia tends to be more extensive on palmar and plantar than on dorsal surfaces. Loss of sensation to moderate pin prick is usually more extensive than loss to cotton wool. Delayed responses to pin prick are common in areas of partial sensory loss. In the hot limbs sensory loss to heat at 40–50° C. is more extensive than to cold at 12° C. Deep pressure sense may be absent. In the great toes vibration sense is often absent, joint position sense usually retained. Several varieties of hyperæsthesia (or "hyperpathia") are found—tingling (e.g., in the digits, elicited or increased by pressure); painful over reaction to light handling or stroking, often in areas insensitive to touch, pin prick or even deep pressure; excessive but perhaps delayed responses to pin prick, causing withdrawal of the foot, in otherwise hypoalgesic areas, muscle tenderness, and tenderness accompanying inflammation (e g, infected blisters)

---

* Based on a lecture given on June 3, 1942, in the "War Medicine Series" at the British Postgraduate Medical School.

(*d*) *Motor disturbances*—Muscles whose points of nerve entry lie within the cooled territory may show weakness, and later wasting and impaired electrical responses, sometimes as severe as in progressive muscular atrophy Recovery is slow (see fig 1) Knee jerks are normal, ankle jerks[†] nearly always obtainable, plantar reflexes absent or flexor

(*e*) *Absence of sweating*—Tests by the method of Guttmann (1940) showed anhidrosis approximately coinciding in extent with sensory loss (fig 2) During recovery, sweating returns rather more quickly than sensation to light touch and moderate pin prick

(*f*) *Blisters, ulcers and gangrene*—Many mild and a few moderately severe cases do not show blisters Blisters may appear during the first 3 days after rescue, or not until the 8th to 10th day (fig 3) Healing often takes 3–6 weeks, occasionally 3–5 months Parts which are to become gangrenous blister extensively The affected skin, often thick and hard, later peels extensively Hairs may be lost, toe nails shed painlessly Parts of the skin are blackened and flake off leaving pink dermis, or perhaps small ulcers Gangrene, if present, is nearly always superficial, even if the whole foot is black, tissue loss may be confined to the tips of the toes, which are shed like thimbles In one severe case, distal parts of the feet separated at 7 weeks, pain persisted and the legs were ultimately amputated

Other clinical findings were occasional transient albuminuria after rescue, loss of weight, gradually regained, mild tachycardia, pyrexia up to 99 5° F, sometimes for several weeks, and minor variations in the leucocyte picture Respiratory infections and alimentary disorders were rare

3. The *posthyperæmic stage* lasts for weeks or months after the hyperæmia has subsided Except for fresh blisters or infections, the extremities are no longer unduly hot in a normal environment Indeed for months or years after rescue there may be a cold-sensitive state, giving rise to the Raynaud phenomenon, or to coldness which may last for hours after return from a cold to a warm environment Swelling of the feet may recur when walking is resumed Tingling and pains have usually ceased and sensation is slowly returning Over-reaction to pinprick is common, especially in the sole There is gradual improvement in power and electrical reactions, and disappearance of wasting (fig 1) After 6–10 weeks there are often complaints of excess sweating, or of sweat rashes; on a hot day socks are quickly soaked, but extremities may sweat heavily even when cold Local faradism and painful stimuli—e g pinprick in "hyperæsthetic" areas—cause well-marked sweating of similar distribution, in or adjacent to areas previously anhidrotic (cf Guttmann 1940) Blisters may recur after the patient returns to normal footwear and long walks

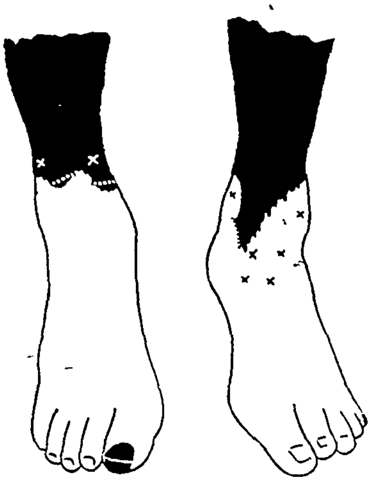

Fig 2 —Distribution of sensory loss and of anhidrosis in another moderately severe case in the hyperæmic stage Dotted line and crosses mark the upper levels for sensory loss to light touch of cotton wool and to moderate pin prick respectively Black areas indicate heavy sweating, dotted areas moderate sweating and unshaded areas absence of sweating (sweat test by chinizarin method, Guttmann 1940) In the right great toe the black area indicates the site of superficial gangrene

COURSE, PROGNOSIS AND SEQUELÆ

The mildest cases in our series had swelling, tingling, pains and sensory loss, recovering completely in 2–5 weeks, few of them were observed during their whole course, but some reported transient warmth and redness of the feet Most other cases passed through prehyperæmic, hyperæmic and posthyperæmic stages, recovering more or less completely between 3 and 12 months after exposure, many showed late sequels during the second year

Findings shortly after rescue gave little indication of ultimate progress Swelling, heat and redness, tingling and pains were of no prognostic value If paralysis and extensive sensory loss persisted into the third week, recovery took many months Blisters and gangrene have been discussed, amputation, even of toes, was rarely necessary

Follow-up for two years in 18 moderately severe cases showed that 7 were doing full duty, 2 had been invalided, and the rest were doing light duty such as office work Sequels, mostly transient and related to prolonged standing or walking in cold or wet weather, included tingling, usually slight (in 7 cases), aching or stabbing pains, often slight (in 15 cases), and swelling of feet (in 8 cases) A few had fresh blisters A foot originally damaged to the extent of superficial gangrene occasionally developed "trophic" ulcers and bone and joint changes in the digits (sequestra, hammer toes), with circulatory defects suggestive of vascular occlusion Typical intermittent claudication was not encountered A cold-sensitive state and troublesome hyperhidrosis sometimes persisted for 2 years after rescue

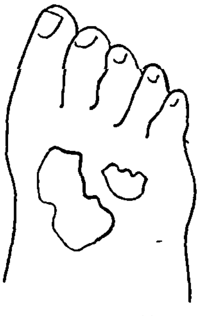

Fig 3 —Site of blisters, healed at 3 weeks in a case of immersion foot

CAUSATION, INCIDENCE AND PREDISPOSING FACTORS

The essential cause of these disturbances is exposure of the limbs to cold insufficient to freeze the tissues, probably sea temperatures ranged from –1 9° C to 10° C Sea water freezes at –1 9° C, and tissues do not freeze until their temperature falls to –2 5° C or less, so that parts immersed cannot be frost-bitten Immersion has no specific action apart from its effect in keeping the parts cold Sometimes the hands, although not immersed, are damaged as much as immersed feet An exactly similar condition, with muscle wasting, sensory loss, excess sweating and a cold-sensitive state, affected the ungloved hand of an airman who had lain exposed for 22 hours on a snow-covered mountain The term "immersion foot" is therefore inaccurate as well as inadequate The ideal term should be applicable to other tissues as well as to the feet and should express both the causative factor—cold—and the neural and vascular disturbances which result therefrom—i e, a peripheral vasoneuropathy after chilling

Judging from the patients' histories, the following factors appear to influence the occurrence and severity of this vasoneuropathy

1 *Time of exposure and temperature of water*—With sea water temperatures of 5–8° C, periods as short as 22 hours, and in one instance 14 hours, were sufficient to cause nerve damage[‡]

2 *Footwear* afforded some protection during short exposure, immersed 14 hours at 5° C, an airman's left foot, covered by four socks, was less affected than the right, which had one sock During long exposure, however, boots constricted the swelling feet and impaired their circulation, a booted foot often suffers more than one from which the boot is lost Rubber sea-boots filled with water or sweat

3 *Immobility*—Men who kept moving suffered less than those who sat still Mechanical interference with circulation accentuated the condition A man whose left knee was damaged sat with his left leg straight, keeping the right leg doubled under him, immersion foot was more severe on the right side An airman exposed for 14 hours in a rubber dinghy, holding tight to the centre rope had more severe nerve damage in the hands than in the feet, which were also immersed in water

4 *Body cooling*, as from wind, total immersion, repeated soakings or inadequate clothing, reduces the peripheral circulation

---

[†] The possibility of these being absent in the prehyperæmic stage is not excluded

[‡] In cold so severe that sea water partly froze even 20 minutes immersion was followed in 2 instances by swelling blisters and neural lesions parts affected were not constantly immersed however and were exposed to air long enough for actual freezing (frost bite) to have taken place

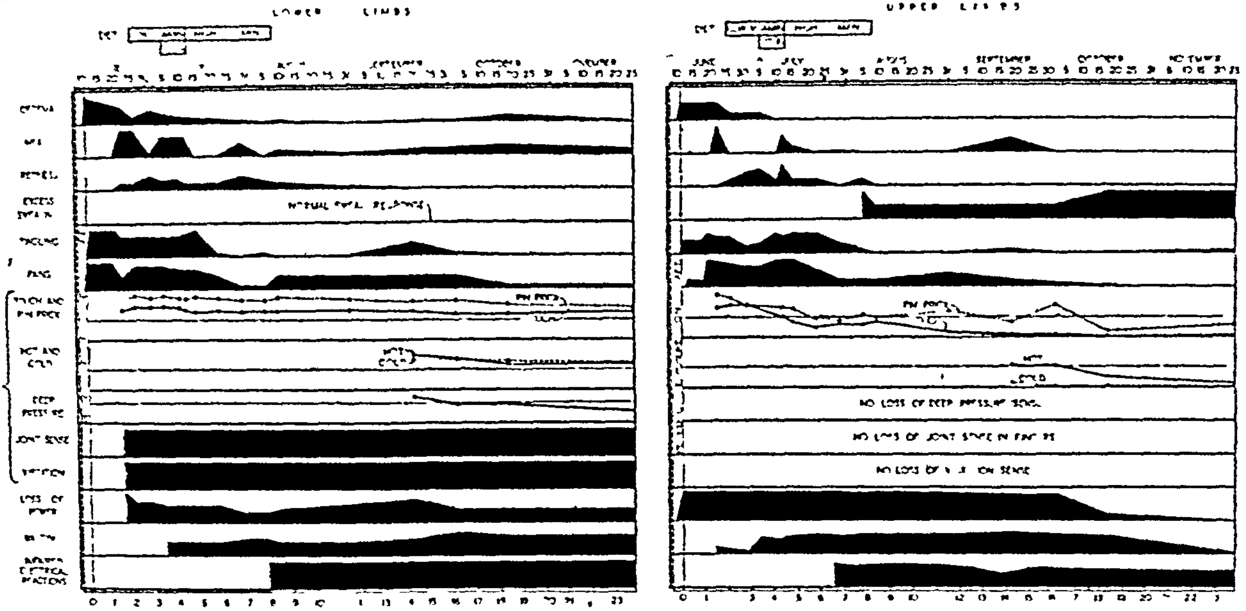

Fig 1.—Progress charts in a rather severe case of immersion foot and hand For sensory tests the extremities were divided into numerous small areas total number of areas affected was charted Progress was not influenced by the administration of vitamin B_1 or other vitamins during the periods indicated

5 *Seasickness and starvation* may be contributory

6 *Age*—Men over 40 and under 17 died from cold sooner than those of intermediate age Within the latter group, which included most cases, age and severity were not closely correlated

7 *Race*—Coloured races are said to be more prone to trench foot than northern races In this study, Arabs fared no worse than Europeans

8 *Morale*—Those who give up hope die more quickly, or suffer more severely, than their companions

9 *Treatment on rescue*—(See under pathogenesis)

There was no evidence that previous susceptibility to cold feet or chilblains predisposed to immersion foot

ALLIED CONDITIONS

Frost-bite due to actual freezing of tissues, was seen in only 3 cases in this series After chopping ice from the deck for 4 hours, a seaman developed gangrene in the ends of the fingers of the ungloved hand which held the axe A man, exposed for 3½ days at sea-freezing temperatures, suffered gangrene of the fingers holding a bailer, another in the same boat developed gangrene of the skin on which he knelt to bail These frost-bite lesions presented an interesting contrast to those of immersion foot and hand Gangrene involved the whole thickness of affected digits, and although parts just proximal to the gangrene were hyperæmic, they were not unresponsive to vasomotor control, and not insensitive to touch or pin-prick The area of sensory loss and anhidrosis over the front of the knees in the third case was only slightly more extensive than the scars which resulted from the gangrene In this and in the second case, frost-bite and immersion foot coexisted, heightening the contrast between them, the feet immersed and therefore protected from frost-bite, showed the typical vasoneuropathy of immersion foot, and no gangrene apart from superficial necrosis of a toe (fig 2)

Œdema of the feet, sometimes lasting several months, was seen in men who spent long periods in open boats with insufficient food or drink in strong sunlight, with their legs immersed in warm sea water (18–20° C) The neural and vascular features of immersion foot which are directly due to cold were absent

MORBID ANATOMY

The material available consisted of biopsies from the interdigital nerves of the foot 2½ and 4 months after exposure, and of lower limbs, in which gangrene and sepsis had been present, amputated 4 and 11 months after rescue The interdigital nerves showed almost complete wallerian degeneration and no significant vascular change The tissues of amputated limbs showed a persisting œdema The main nerve trunks showed severe degeneration and early regeneration, in the larger arteries there was slight intimal and medial fibrosis, in the large veins (1 case) patchy organised recanalised thrombus Small vessels were not significantly abnormal The muscles showed degenerative changes more severe than those following denervation

PATHOGENESIS

Vascular changes—Impressions of the state of the vessels during exposure and just after rescue are based on limited observations in the prehyperæmic stage, and on analogy with conditions during general and local hypothermia

During general hypothermia collapse of peripheral venous channels is noticed first With continued hypothermia, constriction of the large arteries occurs The blood pressure and peripheral pulse may be unrecordable for several hours, yet neither vascular occlusion nor thrombosis is a complication Blood continues to flow in the arterial channels because arterial punctures are possible (Talbott 1941)

Coldness of the affected parts in the prehyperæmic stage indicates narrowing of arteries or arterioles That large arteries are narrowed is shown by the absence of peripheral pulses, in one case pulsation returned in the left dorsalis pedis 2½ hours after rescue, and 4 hours after rescue in the right This observation also suggests that the vessels are narrowed by contraction or œdema of their walls rather than by obstruction by clot This narrowing is attributable to the action of cold, direct or through the nervous system (see Pickering 1932) Intimal changes in vessels may in some cases lead to thrombosis, although, according to Allen (1941), cold seems to inhibit intravascular clotting Judging from the findings of Brooks and Duncan (1940b), however, it is probably not necessary for the production of gangrene that ischæmia should be complete, or that thrombosis should occur Indeed, vessels may remain patent, and their contents fluid even after gangrene has set in

The transition to the hyperæmic stage often occurs suddenly, presumably when warmth to the body and limbs overcomes the vasoconstriction which resulted from cold The excessive vasodilatation which follows may be due to three factors—inflammation, damage to vessels and vasomotor paralysis Inflammatory response to damage by cold is recognisable in tissues exposed at temperatures below 15° C (Lewis 1941), and would explain early hyperæmia, swelling, pain and tenderness Heat and redness in relation to blisters, gangrene and infections at any stage are also inflammatory Direct damage to vessels by cold or ischæmia is a possibility Such damage to arterioles, if present, cannot be great, for the arterioles (see below) retain their ability to respond to circulating adrenaline Damage to capillaries, however, may explain both the persistent tendency to œdema and the intensity of skin colour, which, deepening on dependency of the limb and blanching on elevation, indicates a dilated capillary bed § Finally, the vasodilatation may result partly from interruption of vasoconstrictor fibres in the peripheral nerves In cases of immersion foot in the hyperæmic stage during exposure of the body in a cool room, the extremities remain hot instead of cooling, and their temperature is not significantly altered by immersion of other limbs in hot or cold water—i e , vasomotor reflex responses are absent

In one experiment, the external popliteal nerve was blocked with local anæsthetic In spite of the completeness of the block as indicated by the resulting anæsthesia, analgesia, anhidrosis and muscular paralysis, there was no rise in temperature in the skin of those parts of the dorsum of the foot and toes whose vessels are normally under the control of vasoconstrictor fibres from the external popliteal nerve ‖ In the same patient, skin vessels of an affected extremity were shown to be hypersensitive to physiological amounts of circulating adrenaline secreted in response to insulin hypoglycæmia Similar vascular hypersensitiveness to circulating adrenaline is known to occur 8–10 days after post-ganglionic sympathectomy, when the vasoconstrictor fibres have degenerated

These findings do not in themselves prove the existence of vasomotor paralysis , any inflammatory reddening might behave similarly There is, however, supporting collateral evidence Histologically, degeneration is seen in about 90% of nerve-fibres in affected nerve trunks, and clinically there is evidence of degeneration and regeneration in fibres conveying motor, sensory and sudomotor impulses , accompanying vascular phenomena suggest that vasoconstrictor fibres are also involved After the nerves have had time to degenerate, faradic stimulation does not give rise to sudomotor and pilomotor responses (in the feet, however, pilomotor responses may be unobtainable even in normal individuals) As after sympathectomy, electrical resistance of the skin is greatly increased Events during the posthyperæmic stage (see below) are also significant , cooling (perhaps with a cold-sensitive state), partial recovery of sensation (with hyperpathia) and of sweating (with marginal hyperhidrosis) appear after the same interval, as if all were dependent on one factor , this factor may be partial re innervation of the end organs or effector organs concerned

In the posthyperæmic stage the skin may become cooler before reflex vasomotor activity is regained Most of this cooling is probably due to lessening of inflammation , some may be due, however, to an increase in intrinsic arteriolar tone such as is known to occur 2–3 weeks after post-ganglionic sympathectomy or after section of peripheral nerves containing vasoconstrictor fibres (White and Smithwick 1942) After immersion injuries, in which factors other than nerve damage play a part, this recovery of vascular tone tends to come later than after sympathectomy The skin vessels of the cool limb, even if not yet under nervous control, are capable of dilating in response to tissue damage as from burns or infections When the damaged vasomotor nerve-fibres have regenerated reflex nervous control returns During or after this regeneration, the vessel walls may display a hypersensitiveness to cold in the form of Raynaud's phenomenon, or of delay in vasodilatation following return to warm environment ¶

Changes in nerves —The extensive cutaneous anæsthesia observed just after rescue might be due to a combined effect of cold and ischæmia That cold can act directly on nerve-endings is suggested by unpublished observations of Lewis , after cooling a portion of skin, anæsthesia developed rapidly and it fitted accurately and was limited to the area cooled The action of cold on nerve trunks was demonstrated by Bickford (1939), cooling the ulnar nerve blocked its motor, sensory, vasomotor and sudomotor impulses It is necessary, however, to distinguish between the effects of temporary interruptions of nerve-impulses and those of actual damage to nerves No record has been found of nerve degeneration experimentally produced by cooling, short of freezing, with the blood-supply intact

Lake (1917) observed that cultures of embryo tissues, including nerves, derived from warm blooded animals, were destroyed by temperatures of −6° C or less, and were adversely affected by temperatures between 5° and 15° C , but were not damaged by storage at or near 0° C These experiments on isolated tissues, although interesting, are not necessarily applicable to nerves in the intact organism Talbott (1941) states, however, that during local hypothermia a circumscribed area of the body may be maintained between 40° and 50° F (5–10° C) for several months without damage or destruction of normal tissues , perhaps because, so long as the rest of the body is kept warm, circulation through the cooled part is not interrupted

On the other hand, ischæmia of a limb without cooling results in motor, sensory, vasomotor and sudomotor paralyses, and if ischæmia is prolonged the nerves degenerate In acute experiments, at least, sensory loss is of the glove and sock type, more extensive on palmar and plantar than on dorsal surfaces (Lewis 1931), a distribution similar to that found in immersion foot Quickly reversible damage by anoxia might account for proximal parts of the extensive anæsthesia found just after rescue, less transient anæsthesia in distal parts being due to more serious nerve damage Little is known of the duration of ischæmia needed to produce nerve degeneration , it is probably less than that necessary for gangrene

Ligation of rats' hind limbs for 4–4½ hours caused sensory loss and paralysis of a duration compatible with degeneration and regeneration (Allen 1938) Highet and Holmes (1942) produced complete wallerian degeneration of the sciatic nerve by 3 hours' tight ligation of the rabbit's hind limb, the sciatic nerve being excluded from the ligatures

In these two sets of experiments arterial spasm probably persisted long after removal of the ligatures (cf Barnes and Trueta 1942) , the duration of ischæmia needed for nerve degeneration may thus be much more than 3–4½ hours

Ischæmia, combined with cold, takes longer to produce nerve degeneration or tissue necrosis than does ischæmia without cooling

Bloodless limb tissues, which die in 12–15 hours at room temperature, will if cooled to 5° C survive for over 50 hours without subsequent gangrene (Allen 1941) In rats' tails rendered anæmic by pressure of 130 mm Hg, cooling to 5° C increased the period needed to produce gangrene from 14–18 hours to 48–96 hours , at both high and low temperatures, periods of complete ischæmia less than those necessary for massive necrosis led to extensive fibrous replacement of muscles and nerves (Brooks and Duncan 1940a) Incomplete ischæmia from pressures less than 130 mm Hg also damaged muscles and nerves, although after a longer time (Brooks and Duncan 1940b)

The importance of differences in the degree of ischæmia is stressed by Highet and Holmes (1942), who repeated the procedure of Griffiths (1940)—ligation of the common iliac and common femoral arteries—in an endeavour to produce Volkmann's ischæmic paralysis

Highet and Holmes found, according to the completeness of the ischæmia attained, (1) nerve degeneration , (2) nerve degeneration with necrosis and contracture of muscles , or (3) nerve degeneration with gangrene of the extremity Demyelination appeared a little earlier than axonal disintegration, and at proximal levels might be present where axons were intact They were unable to produce, in rabbits, extensive fibrosis (collagenisation) of nerves such as they found in long standing cases of Volkmann's paralysis

---

§ It is at first sight surprising that this intense colour, in warm skin, is tinged with blue Blood flowing rapidly through dilated skin capillaries could be bluish only if oxygen were being abstracted from it even more quickly than occurs in inflamed skin, which is unlikely It is more probable that the blood flow through the capillary bed is somewhat slow allowing excessive abstraction of oxygen, and that the warmth of the skin is due to rapid flow of blood through widely patent arterio venous shunts (the result of denervation Clark 1938) in the peripheral parts, and through the superficial veins into which they drain

‖ Nerve block is used in this way to test the completeness of a sympathectomy (White and Smithwick 1942) Although in the test described above the skin of the parts was already warm (28–31 C) the absence of any further rise in temperature after nerve block suggests that the vessels before the nerve was blocked were not receiving any vasoconstrictor impulses

¶ Unpublished observations of R T Grant are in keeping with the suggestion that partial re innervation of vessels may be responsible for the cold sensitive state and for the development of Raynaud's phenomenon.

In immersion foot, mode of recovery and histological findings spoke against extensive fibrosis of muscle and nerve As already indicated however, absence of fibrosis does not exclude ischaemia as a factor in nerve damage

The final verdict must await more definite evidence, particularly as to the direct effect on nerves of prolonged cold, short of freezing with the blood-supply intact Meanwhile one must regard ischæmia, probably incomplete, and with its action retarded by cold, as the most likely cause of nerve damage in immersion foot

The delaying effect of cold, in the experimental work just quoted, makes it surprising that nerve degeneration should have occurred at all, as it did in some cases, after so short an exposure as 22 hours, or in one instance 11 hours at 3 5–5° C The explanation may be that, while the limb is being warmed after rescue the temperature of the tissues including the nerves is raised by heat applied from without before their blood-supply is restored by relaxation of the main arteries, their oxygen requirement then greatly exceeds the supply (intervals of 2½ and 4 hours between rescue and reappearance of dorsalis pedis pulse have already been referred to) During a few hours of coincident warmth and ischæmia, after rescue more damage may be done than during the actual exposure There is already clinical experience that rapid warming of chilled limbs after exposure is deleterious and in some countries it is customary to keep such limbs cool with ice or snow while warmth is applied to the body This point, with its obvious bearing on treatment, calls for further experimental investigation **

Changes in skin —Blistering must be regarded as a reaction of the cells and small blood-vessels of the skin to damage by cold, although maceration of skin by imbibition of water may play a part Increased capillary permeability and increased blood-flow in the hyperæmic stage, producing a general tendency to œdema, may contribute to the production of blisters, this may help to explain why in some cases blisters do not appear until the 8th or 10th day after rescue, though in others they are seen during the first 3 days In general, the incidence of blistering is irregular and unrelated to the severity of the damage to vessels and nerves, its occurrence in the late hyperæmic and posthyperæmic stages, if patients have walked too much or worn tight shoes, suggests that in these cases minor local trauma may be the determining factor

PROPHYLAXIS AND TREATMENT

Once cold and wet penetrate, boots should be discarded before they become tight The value of greasing the skin is limited Rubbing with oil aids circulation temporarily, but may damage anæsthetic feet Active movements are valuable, postures impeding circulation should be avoided (see also under causation)

The rescued man must be carried, not allowed to walk on damaged feet The aim is to warm his body, keeping the extremities cool Stripped of wet clothing, he is wrapped in blankets, hands and feet exposed He is given hot drinks, but not left near a fire or in an overheated room Hot bottles to the feet and washing in warm—even luke-warm—water are forbidden

The feet, insensitive and fragile, may be seriously damaged by "trivial" injury Massage is contraindicated Patients are kept in bed, sometimes for many weeks, early walking may cause excoriation, blistering or increased swelling Feet are raised on pillows, exposed to the air, and kept dry Sulphanilamide powder may be applied to wounds and blisters Beneficial results from "dry cooling" the hot limbs with fans or ice bags are reported from Canada The following instructions are given to convalescents

> "Use well fitting shoes or boots Look out for inwardly projecting nails Change your socks daily Sprinkle inside your socks some talcum powder mixed with boracic powder (3 parts to 1 part) Do not walk long distances Remember your feet are still insensitive and may easily blister without your feeling discomfort You may wash your feet or take a bath, but avoid putting your feet into anything but luke warm water Dry thoroughly after washing If your feet swell or show signs of blistering or redness, rest in bed and get medical advice Nails to be cut straight and with great care to avoid injury to the skin Do not cut corns or apply caustic to them Treat your feet as if they were made of porcelain Be on your guard to prevent others damaging your feet by treading on them"

SUMMARY

Men exposed in open boats or rafts, with their limbs immersed in sea water at –1 9° to 10° C, may show evidence of damage to peripheral vessels, nerves, muscles and skin A similar condition may affect extremities exposed to cold without immersion, provided the degree of cold is insufficient to cause frost-bite

After a short prehyperæmic stage there is a stage of hyperæmia in which the affected parts become hot, red and painful, more swollen and perhaps blistered Gangrene, if present, is nearly always superficial In severe cases the results of nerve degeneration in the cooled tissues are evident in sensory loss, motor, vasomotor and sudomotor paralyses

In the posthyperæmic stage inflammation subsides vascular tone recovers, the skin temperature falls and the vessels may become hypersensitive to cold By this time the patient is usually free from swelling, pain and tingling Complete recovery, which must await regeneration of peripheral nerves, is preceded by signs suggesting partial re-innervation of end organs and effector organs—cooling (with a cold-sensitive state) partial recovery of sensation (with hyperpathia) and of sweating (with marginal hyperdrosis)

Late sequels included recurrence of pain, tingling, swelling or blisters, persistence of a cold-sensitive state or of hyperhidrosis, and occasionally circulatory defects suggestive of vascular occlusion

Probably injudicious warming of affected limbs after rescue accentuates damage by raising the metabolic demands of the tissues while they are still ischæmic For some hours after rescue such limbs should be kept cool while the patients' bodies are being warmed

The work is still in progress, and some statements made here may need correction or amplification, more pathological material and more observations in mild cases and earlier stages are needed, and certain experimental findings need confirmation

Acknowledgements are due to Surgeon Rear Admiral H E R Stephens for permission to carry out this work, to Temporary Surgeon Rear Admiral J W McNee, Surgeon Captain Macdonald Critchley, Air Commodore C P Symonds, Prof J R Learmonth, Dr R L Richards, Dr J B Gaylor and Dr S Bartlett for certain case records, and to these and many others, including Prof R S Aitken and my Naval medical colleagues at the hospital, for help and advice,

MEDICAL HONOURS —The DSO has been awarded to T/Surgeon Lieutenant M P Martin, MRCS, RNVR and the DSC to Prob T/Surgeon Lieutenant T P Storey, MRCS, RNVR, for gallantry, daring and skill in the combined attack on Dieppe The RNVR officers' decoration has also been awarded to acting Surgeon Commander J B Hutchison, FRCSE, and to acting Surgeon Commander D W Bawtree, FRCSE

** Exudation, especially in chilled limbs which have been rapidly warmed, is another possible cause for damage to nerves (*cf* Lake 1917 Smith Ritchie and Dawson 1915) In the present investigation however there was no obvious correlation between exudation and nerve damage anæsthesia was more extensive in the prehyperæmic stage, when swelling was slight, than in the hyperæmic stage when swelling had often greatly increased

INFECTIOUS MONONUCLEOSIS

LAWRENCE KILHAM
M D HARVARD
PHYSICIAN

ALEX J STEIGMAN
M D TEMPLE
CHIEF PHYSICIAN

AMERICAN RED CROSS HARVARD FIELD HOSPITAL UNIT

THE unit has recently cared for 20 patients with infectious mononucleosis in a period of eight months This series illustrates the protean manifestations of a disease the ætiology of which continues to be obscure and the serology unexplained

Distribution —The group of patients was equally divided between the sexes , 16 of the cases were between 18 and 25 years of age, the age-limits being 10 and 34 years All but 4 of the patients were in the Armed Services With an average of 2 or 3 admissions per month from November, 1941, to June, 1942, seasonal variation was not evident

Onset and duration—In 3 patients the onset was sudden , in the remainder it was gradual The duration of the disease varied irregularly between 8 and 25 days Clinical improvement was fairly rapid—a matter of a few days in nearly a third of the cases It was more gradual in the remainder

Symptoms —Fatigue was commonly one of the first symptoms noted A sore throat was complained of by all but one patient, while headache, a swelling and tenderness of cervical lymph-nodes occurred in the majority The cervical lymph-nodes in some produced pain and stiffness of the neck Four jaundiced patients had nausea and epigastric discomfort, associated in one case with vomiting These symptoms occurred in only one of the non-jaundiced cases Severe lumbar pain developed in one patient with hæmaturia The degree of fever varied, being low-grade or of short duration in 15 patients , 2 patients showed well-marked daily fluctuations between 99° and 103° F over a 10-day period and 2 others had a low-grade fever persisting for nearly 2 weeks , 1 patient had a sustained pyrexia of 102° to 103° F , which fell by crisis after 6 days

PHYSICAL FINDINGS

Skin —Rashes appeared in 5 of the 20 cases This incidence is higher than that encountered by Bernstein (1940), 9% of 65 cases, or by Sadusk (1941) 4 of 54 cases These rashes were of three types , morbilliform, scarlatiniform and erythema iris A morbilliform rash occurred in 3 cases, in each of which there was an associated jaundice In 2 of the cases this rash appeared on the 7th day of the disease It consisted of coppery maculopapules, extending over the trunk and down the extremities to the backs of the hands and feet These lesions, lasting 3 to 4 days, were at first discrete and then merged into large confluent blotches, particularly on the trunk , palms and soles were spared In 1 patient a morbilliform rash developed on the 16th day and was limited to the elbow regions These morbilliform rashes left a transient brownish discoloration of the skin Itching was slight A scarlatiniform rash occurred over the trunk and abdomen of 1 patient on the 6th day of the disease and faded in a few days An erythema iris type of rash developed in another patient on the 6th day It began with redness and tingling of the hands , next day white swellings 1–2 cm in diameter and surrounded by reddish rings appeared, chiefly on the palms This rash persisted for 10 days

Eyes —Seven of 20 patients had hyperæmia of the conjunctivæ at some stage of their illness Two patients had puffiness of the eyelids , in 1 of these the œdema of the lids was associated with extreme enlargement of the cervical lymph-nodes and possibly was due to pressure on the jugular veins

Oral cavity —Petechiæ were present over the oral mucosa in 8 cases , 3 of these had a concomitant morbilliform rash and icterus One of these 3 had extremely numerous petechiæ in the mouth and hæmaturia , he had no additional hæmorrhagic phenomena Another type of mouth lesion consisted of tender irregular red papules over the hard palate, measuring 0 5 cm in diameter, which occurred in 1 case These were discovered on the 14th day, when the patient complained of soreness of the mouth , they lasted 3 days

Tonsils and adenoids —Enlargement of the tonsils was present in 17 of the 20 patients Two patients, the most severely ill in the entire series, had tonsils meeting in the midline, which caused considerable difficulty in swallowing An easily removed grey-white membranous exudate covered the enlarged tonsils in 10 cases In no patient did membrane occur without tonsillar enlargement Adenoid enlargement was suggested in 4 cases—a child and 3 adults—all of whom developed almost complete nasal obstruction and an adenoid tone of voice A lateral X ray of the head and pharynx in one of these cases demonstrated enlarged adenoids

Lymph-nodes —Enlargement of the cervical lymph nodes, particularly at the angles of the jaw, was common to all cases These nodes were often tender Axillary, epitrochlear and inguinal lymph-nodes were less constantly involved Characteristically, the enlarged nodes regressed rapidly in size, once general recovery had set in

Spleen and liver —The spleen was palpable in 11 patients by the 2nd week of their illness. Often no enlargement was detectable in the first week In some instances the spleen, not palpable with the patient in a recumbent position, was felt with the patient in the right lateral position with the knees drawn up and the left arm thrown to the right side of the bed In all cases but one the splenic edge was palpated just below the left rib margin The exception had a tender splenic edge 3 fingerbreadths below the costal cage He was also severely jaundiced and had a tender liver edge extending to the level of the umbilicus No other instances of hapatomegaly were encountered

Jaundice —Seven patients had jaundice , 4 of them had clinical jaundice and, as discussed below, 3 others had laboratory evidence of subclinical icterus Clinical jaundice developed in the latter part of the first week of illness in 3 patients A fourth patient became icteric on the 16th day As noted above, a morbilliform rash and oral petechiæ accompanied 3 cases with clinical jaundice

LABORATORY FINDINGS

Heterophile antibodies —Three types of heterophile antibodies are found in human sera, which agglutinate sheep erythrocytes These are differentiated by whether or not they are absorbed by oxerythrocytes or guineapig kidney One type, found in normal sera, is not absorbed by either reagent, whereas the type found in human sera after horse-serum injection is absorbed by both In infectious mononucleosis, the diagnostic heterophile antibodies are absorbed by oxerythrocytes but not by guineapig kidney The new modification of the Paul-Bunnell test, suggested by Barrett (1941), differentiates these three types of antibodies It was used in the serological diagnosis of all 20 patients in the present series By this test sheep-cell agglutinins in a titre of 1 40 or above are considered diagnostic, if they are absorbed by oxerythrocytes In this group of 20 cases all had a titre of 1 160 or higher, except for a single titre of 1 80 The Barrett test was repeated in 6 cases In all of these the titres of the later sera showed a rise during the 2nd or 3rd week In 2 cases the sheep-cell agglutination test was negative during the 1st week but repeated tests gave strongly positive results at the beginning of the 3rd week The sera of 4 patients had titres reaching a height of 1 2560, 2 in the 1st week and 2 in the 3rd week There was no constant relationship between the height of the titre and the clinical severity of the illness Unfortunately, the duration of the elevated heterophile antibody titre could not be followed owing to the mobility of the military population One of our hospital employees, however, had a titre of 1 80 three months after the onset of her illness

Leucocytes —There was a leucocytosis in all cases at some time during the first 2 weeks Within this period every individual reached a total leucocyte count of 10,000 per c mm or above The peak of the leucocytosis might occur in the 1st, 2nd or 3rd week, there being no regularity among the cases Leucocyte counts ranged from 4300 to 32,000 per c mm

Two patients had an initial leucopenia One of these had a total leucocyte count of 4300 per c mm on the 10th day, which rose to 21,000 per c mm on the 19th day The polymorphonuclear neutrophils in this case showed the greatest fall, numbering 1720 per c mm on the 10th day Another case was similar, with 1760 polymorphonuclear neutrophils per c mm in a total leucocyte count of 5200 per c mm on the 7th day In this last case the total white count was 15,000 per c mm a week later

It has been suggested that the so-called anginose type of infectious mononucleosis is due to a granulocytopenia Among our cases 9 had granulocyte counts below 2000 per c mm, the lowest being 900 per c mm The 2 severest anginose cases had normal or slightly increased polymorphonuclear counts of 4500 and 6800 per c mm In all of our patients there was a relative or absolute decrease in polymorphonuclear neutrophils, whereas in many instances the degree of secondary infection had led one to expect a considerable polymorphonuclear response A suppression of polymorphonuclears therefore appears to have been present Barber (1941) found similar granulocyte counts reaching as low as 960 per c mm in a series of 7 patients who had the anginose type of disease

The percentage of mononuclear cells ranged from 68% to 78% as the maximum response in each patient All smears showed varying numbers of atypical lymphocytes We do not feel, however, that there is any one particular cell type peculiar to, or specifically diagnostic of, infectious mononucleosis The chief characteristic of the "atypical" lymphocyte, as stated by Bernstein, is its variability Among the salient features common to many of the atypical lymphocytes are a deep and coarsely staining nucleus, which often shows fenestration and an irregular shape The cells are all roughly the size of large lymphocytes

Liver studies —The van den Bergh test gave a direct reaction in 5 patients, all of whom showed bile in the urine Three patients with obvious jaundice had serum levels of 4 5–7 5 mg of bilirubin per 100 c cm and a 4th patient had minimal jaundice with 1 4 mg per 100 c cm The 5th patient was deeply icteric, on the 11th day of his illness his cholesterol was 285 mg per 100 c cm, phosphatase 26, Bodansky units and bilirubin 1 5 mg per 100 c cm The low serum bilirubin was associated with a fading icterus A liver-punch biopsy specimen was reported as follows by Prof J H Dible of the British Postgraduate Medical School

> The sections show a well marked focal acute hepatitis The maximum change is seen in the portal tracts of the lobules where there is loss of liver cells and a well-developed histiocytic reaction with some early proliferation of bile-ducts There are also isolated foci of similar histiocytic reaction in other parts of certain of the lobules and the sinusoids show an excess of cells, some of which are Kupffer cells and others resemble monocytes The glycogen content of the hepatic cells is well preserved and the general appearances suggest that an earlier phase of necrosis has preceded the present histiocytic reaction The reticular pattern of the lobules is disturbed in the affected portal zones but there is no true fibrosis

Urine —Bile was demonstrated in the urine of 7 cases, 4 of whom were clinically jaundiced One patient had hæmaturia, showing 10–30 erythrocytes in the spun sediment throughout the 3rd week of his disease There was no indication that any other cause was responsible for the hæmaturia He had a normal intravenous urogram and had received no sulphonamides

Throat cultures in 12 cases demonstrated wide variation, 4 showing the usual throat flora *Streptococcus pyogenes* belonging to various groups occurred in the other cases One case showed *Strep pyogenes* group A, another showed group C, type 21, and 3 cases showed *Strep pyogenes* not belonging to groups A, C or G Three patients had pharyngeal cultures showing *Strep viridans* No one organism was common to any significant number of cases Eight cultures for *Corynebacterium diphtheriæ* were negative Fusiform bacilli and spirilla were looked for in two cases and found in both

Cerebrospinal fluid —Lumbar punctures gave negative results in 2 of 4 cases subjected to this procedure One patient had a distinct encephalitis, as evidenced by severe headache, well-marked drowsiness, nuchal rigidity and an irrational state He had 56 white cells per c mm of spinal fluid, 80% of which were lymphocytes, protein and pressure were normal Another patient without meningeal signs or symptoms had 30 leucocytes per c mm of spinal fluid, again chiefly lymphocytes, protein and pressure were normal

Sedimentation rate —This examination performed in 4 cases in an active stage of the disease was within normal limits for 3 cases and slightly elevated for the 4th case The 4th case was the only one having pyrexia, which was slight

Serology —Hinton tests (a flocculation test for syphilis) was done in all cases and were negative in the entire group Wassermann reactions done in 9 cases were positive in 1 This patient was positive on the 11th day, but negative on the 19th day With 2 exceptions only 1 of either of these examinations was carried out in the individual case As the state of positive serology is known to be transitory often lasting only 3–4 days, repeated tests might have yielded different results

TREATMENT

Treatment was largely palliative Five patients with well marked pharyngeal involvement and showing streptococci in throat cultures received full doses of sulphadiazine (30–40 g in 5 or 6 days) without demonstrable effect on the clinical course Sears (1942) has suggested that sulphonamides may be hazardous in infectious mononucleosis, because of the frequent coexistence of granulocytopenia He cites a case where polymorphonuclears were reduced to 225 per c mm Sulphadiazine was given to 5 patients in our series, in 2, the number of polymorphonuclears was slightly depressed after this drug, and in 2 it was elevated Three cases suspected of diphtheria were given 20 000–60,000 units of antitoxin, again without appreciable effect, but we recommend this treatment where there is any doubt as to the initial diagnosis Scarlet fever convalescent serum, as recommended by Berkeley (1942), was given in 1 case The patient, however, had already shown signs of recovery and no benefit could be ascribed to the serum

EPIDEMIOLOGICAL NOTE

Generally speaking, the infectivity of infectious mononucleosis did not appear to be high Sixteen of the 20 patients were military but all came from different localities without any contact with each other Likely contacts of 2 cases were examined and blood smears and heterophile agglutination tests done Of the 25 contacts, 1 man was found to have a positive heterophile test, but he denied any sort of illness in the preceding 6 months Some epidemics of this disease have been reported but in the main the disease remains one of low infectivity with sporadic occurrences

DIFFERENTIAL DIAGNOSIS AND ÆTIOLOGY

In 6 of 20 patients the diagnosis before admission was correct An equal number were sent in as acute tonsillitis, and 3 of the remainder were considered by their referring physicians to have diphtheria With the present degree of uncertainty concerning this disease a final diagnosis of infectious mononucleosis should be reserved for cases not only clinically compatible but also showing both the hæmatologic and serologic responses Three patients showing well-marked lymphocytosis and glandular enlargement, but without the serologic response, were not considered to have infectious mononucleosis These 3 patients showed persistent lymphocytosis, together with cervical lymphadenopathy The lymphocytes were all small and the sheep-cell agglutination tests negative There were certain similarities in these 3 cases to those described by Smith (1941) as infectious lymphocytosis

One of our patients was referred with the diagnosis of infectious hepatitis, having only the symptoms of catarrhal jaundice More than 50 other men from his same military unit were admitted at about the same time, suffering from an infectious hepatitis Although the patient under consideration resembled somewhat the other cases of his unit, his peripheral blood showed a characteristic lymphocytosis and the heterophile antibody test was positive 1 640 A liver biopsy was performed on this patient, as discussed above

The ætiology of this disease remains obscure Nettleship (1942) has recently reported the production of small white pearly growths infiltrated with mononuclear cells when he inoculated chorio-allantoic membranes with filtrates of nasal washings and whole blood of patients Cerebrospinal fluid from our one case of encephalitis accompanying this disease was inoculated intracerebrally into mice and rabbits and on to the chorio-allantoic membrane of eggs without any positive results

DISCUSSION

The present series of cases seems to indicate that the infectivity and seasonal variation of infectious mononucleosis is not great The military stations from which most of our patients came provided only isolated instances, and there were no outbreaks such as might be expected in other infectious diseases under the conditions of war-time crowding

There seems to be a growing awareness of the diagnosis of this disease About a third of the patients were referred with a correct diagnosis This is a fairly high proportion when one considers the protean manifestations and the similarity to other conditions Werlin and others (1941) list a series of 21 patients, all of whom were sent in with mistaken diagnoses A sheep-cell agglutination test may be negative in the first 2 weeks of the disease, and for this reason repeated tests are indicated in suggestive cases This may explain some cases reported in the past of infectious mononucleosis without a positive heterophile test

We have not found any therapy to be more than palliative Recently Hoffman and others (1942) have reported that sulphathiazole was effective in relieving symptoms in 9 cases They state that in untreated cases symptoms usually continue for 2–4 months This was contrary to our experience, for many of our cases cleared up spontaneously and fairly rapidly in 3–4 weeks We feel that it may often be difficult to impute success to therapy when one considers the variability in duration of the disease Berkeley (1942) has ascribed therapeutic value to scarlet fever convalescent serum on the basis of 4 cases , 3 of his cases obtained symptomatic relief between the 17th and 23rd days of disease We have tried this form of therapy in 1 case Many patients with infectious mononucleosis get well spontaneously in this period, and Berkeley's results are inconclusive

Some believe that a diagnosis of infectious mononucleosis can be made on the basis of lymphocytosis without the presence of atypical lymphocytes, or a positive heterophile antibody test (Reyersbach and Lenert 1941) Abnormal lymphocytes and a positive sheep-cell agglutination test were found in all 20 cases of the present series and both are essential to a proper diagnosis

No published report on the pathology of the liver in infectious mononucleosis has been encountered The presence of parenchymatous changes is interesting in view of the frequent suggestion that jaundice in this disease is caused by pressure of enlarged lymph-nodes on the bile-ducts It must be pointed out that this liver biopsy was taken from a patient who came from a community where an outbreak of another variety of hepatitis was taking place However, this man fulfilled all the rigid criteria for infectious mononucleosis

SUMMARY

Laboratory and clinical data on 20 cases of infectious mononucleosis are reviewed

Four cases had clinical jaundice and 3 showed evidence of subclinical icterus

A liver biopsy showing parenchymatous changes was obtained in one case

The diagnosis of infectious mononucleosis was confirmed in all cases by heterophile antibody tests

The blood smears showed a high lymphocytosis in all cases, and an absolute or relative decrease in polymorphonuclear cells in many

No treatment proved effective

STERILISATION OF SULPHONAMIDES

J E McCartney
M D, D Sc Edin
Major, RAMC

Robert Cruickshank
M D Aberd, M R C P

(*London County Council Pathological Service*)

The recent report [1] of a case of tetanus associated with the local application of a sulphonamide powder has impressed upon hospital authorities the need for issuing sulphonamide compounds for local use in a sterile form and in a sterile container Tests which we have made show that the sulphonamide powders supplied in this country contain sporing organisms and that the cardboard containers in which the powders are supplied are heavily infected with sporing organisms including *Clostridium welchii* We have by a simple procedure been able to issue sterilised preparations of the three common sulphonamides (sulphanilamide, sulphapyridine and sulphathiazole) in a sterile usable container without any apparent physical or chemical change in the powders

TECHNIQUE OF STERILISATION

Wide-mouth screw-capped containers of 1 oz capacity fitted with aluminium caps tightly screwed on, and red rubber washers—the LCC ' Universal Containers '—are sterilised in the autoclave at 15 lb for 20 minutes The sulphonamide powder is obtained from the manufacturers in clean screw-capped glass jars, and not in cardboard containers The assistant who fills the bottles washes up as for a surgical dressing A sheet of sterile kraft paper is placed on the bench, and, with a sterilised teaspoon and a 3-inch glass funnel cut off at the neck, the sulphonamide powder is placed in the previously sterilised universal containers The powder is shaken down until the bottle is nearly full (approximately 10 grammes) and the cap is then *screwed tightly on* When the batch is ready the bottles are placed in the autoclave and heated with the steam issuing freely for 20 minutes The pressure is then raised to 10 lb and allowed to act for 30–60 minutes After removal from the autoclave, the bottles are immediately labelled, a different coloured ink being used on the label according to the contents—green for sulphanilamide, blue for sulphapyridine and red for sulphathiazole For ease in applying the powder a perforated cap may be used as a sprinkler

The rationale of the process is that, although the powder is in a tightly closed container, sterilisation is by moist heat because the powder normally contains 0 2–0 5% of water which in 10 g of material is 0 02–0 05 c cm water The water vapourises and permeates the powder completely as steam, being reabsorbed when the bottles cool down The powder does not cake because there is no addition of moisture, while the comparatively low temperature of 116° C does not alter the colour If the powder is dried in the hot-air oven at 145–160° C the moisture is evaporated, and the heat penetrates only by conduction from one granule of powder to another Moreover organisms are much more resistant to dry heat than to moist heat so that heating must be prolonged for 3–4 hours [2] The method of autoclaving therefore kills the contaminating organisms more easily, quickly, and at a much lower temperature and avoids physical or chemical alteration of the powder

In many hospital sterilisers, sterilisation at a pressure of 10 lb is not very convenient since the valves are set to give higher pressures—15–20 lb The sulphonamide powders may be sterilised at this higher pressure by the procedure outlined above without apparent detriment, except that there may be slight yellowish discoloration At a pressure of 15–20 lb for 20–30 minutes cultures of *Bacillus subtilis* spores dried on lint, enclosed in paper and placed at the bottom or in the middle of the container are invariably killed At the lower pressure of 10 lb for 1 hour, *B subtilis* spores are also killed , at 10 lb for ½ hour not uniformly so

A further advantage of the use of the screw-capped bottle is that when the cap is removed the whole top and lip of the bottle is sterile, having been covered by the screw-cap, and the powder can be poured out of the bottle directly on the wound without fear of contamination. Alternatively a perforated cap may be used which acts as a sprinkler. An important point in the process is to introduce as little extra contamination as possible. Thus, the manufacturer must try to avoid gross contamination in the preparation of the powder, while the bottles are first sterilised and then filled with powder under as aseptic conditions as possible. The fewer organisms there are to kill the easier it is to kill them.

USE IN THE OPERATING-THEATRE

For use in the operating-theatre the following procedure is recommended. The container can be handled by the surgeon under sterile conditions and a perforated cap enables the powder to be sprinkled easily and economically. The rubber washer is removed and a hole ¼ in. in diameter is punched out of the centre of the metal cap. The rubber washer is reinserted and the cap screwed on the bottle which is sterilised before filling with the powder as previously described. After the bottles have been filled and tightly closed, they are marked on the top with a streak of cellulose paint to indicate the contents—green for sulphanilamide, blue for sulphapyridine and red for sulphathiazole. When the paint is dry (in about 30 minutes) each bottle is wrapped in kraft paper (8 in. square), so that the twist of the paper is at the top of the bottle and in the same direction as tightening the screw. A mark may be made on the kraft paper covering with an appropriately coloured crayon to indicate the particular sulphonamide.

The wrapped bottles are sterilised as above and on removal from the autoclave are labelled with a gummed label of the appropriate colour. When the surgeon in the theatre wants a container the nurse untwists the paper from the top of the bottle until the cap and upper part are exposed. The surgeon grasps the top of the bottle and pulls it out of its paper wrapping which remains in the hands of the nurse.

To sprinkle the powder, the cap is removed and the rubber washer pushed out by passing a probe or the points of scissors through the perforation. The cap minus the washer is screwed on the bottle again and the powder sprinkled as required. If perforated screw-caps only are used the bottles after filling must be wrapped in kraft paper and then sterilised and kept wrapped until required, otherwise the tops of the caps will become contaminated by dust and handling. Alternatively, a perforated cap without a washer may be used as a sprinkler. It is wrapped in kraft paper and sterilised with the bottle. When the powder is required the ordinary cap and washer are unscrewed, and the sterile perforated cap is unwrapped and placed on the bottle.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

AT the annual meeting of the association in Nottingham on Sept. 25–26, under the presidency of Mr. G. R. GIRDLESTONE, F.R.C.S., the principal subject discussed was the present arrangements and future plans for

Rehabilitation of the Injured

At Harlow Wood Orthopædic Hospital Mr. S. A. S. MALKIN, F.R.C.S.E., demonstrated the work of the hospital's remedial workshops, and a film was shown illustrating the methods employed there and at a special annexe in the occupational reconditioning of E.M.S. casualty patients. Later at the Rehabilitation Centre for Miners at Berry Hill, near Mansfield, the subject was dealt with from the points of view of the surgeon, the employer, the industrial medical officer and the trade union.

Mr. E. A. NICOLL, F.R.C.S.E., surgeon in charge of the centre, said that the problem was threefold. First there was the purely scientific aspect of physical restoration; secondly the psychological one of obtaining the full coöperation of the patient; thirdly, and sometimes the most difficult, the sociological problem of obtaining the proper social context for the conduction of rehabilitation. As soon as injured every working-man's first desire was to get well as soon as possible. It was when delay occurred that doubts and fears crept in. These must be removed and morale and initiative maintained. Coöperation by the employer, the industrial medical officer and the trade union had produced, in his experience, a team in which the surgeon plays an important part from beginning to end. The result had been the almost complete disappearance of litigation. The statistical difference between a socialised and non-socialised accident service is at least 10% expressed in terms of men returned to pre-accident work, and that was something very considerable when expressed in the return of workmen to the vital man-power of the country.

Mr. GUY DE G. WARREN, speaking as an employer, gave an account of the organisation which was responsible for the development of the Berry Hill Centre. The Midland Colliery Owners Indemnity Association was formed by a group of associated companies to deal with the insurance risks of accident. It was not run for profit and represented the employment of over 100,000 men. With many others they had been shocked by the state of the treatment of injuries as revealed in the report of the British Medical Association committee on fractures. The companies with which Mr. Warren was associated were able, first of all by subsidies, to ensure throughout the area the development of efficient fracture clinics, and this had resulted in an earlier restoration to some working capacity. It was soon appreciated that the lack of facilities for reconditioning prevented men from obtaining full recovery. The job was therefore completed by this rehabilitation centre, and it had been justified from the economic and humanitarian points of view. Any national hospital plan must include similar reconditioning schemes. From his experience he considered that one centre capable of dealing with 60 patients simultaneously should treat and discharge some 500 cases annually. Of accidents in the heavy industries which require hospital treatment, 20% need a course of rehabilitation, so that one unit appears to be necessary for a hospital or group of hospitals dealing with about 3000 such cases annually. On the other hand the percentage of hospital accident cases other than those in heavy industries requiring rehabilitation treatment should not exceed 8% and for these one unit should be sufficient to serve a group of hospitals admitting 8000 such cases a year. The workman must be dealt with in an atmosphere where he knew that everyone from the hospital to the employer was out to help. A man admitted to the centre was given the assurance of the surgeons that he could be improved and afterwards that work would be available for him. The growing utilisation of industrial medical officers in factories would help to foster greater care for the injured man after his return to industry.

Dr. DONALD STEWART, speaking as an industrial medical officer, said that production was now the paramount consideration. It was being somewhat retarded by absenteeism, partly due to injury and sickness. Injuries were seriously increasing, important factors being the amount of new and unskilled labour drafted into industry, often working under overcrowded and other difficult conditions. There was therefore overloading of the casualty and outpatient departments of hospitals in industrial areas, which had to carry on with diminished staffs and with difficulties in obtaining equipment and materials. There was a challenge to hospital services and the medical profession to see that an adequate service was maintained for people in production. Particular problems were provided by young persons and married women in industry and by factory accidents at night-time and on Sundays. The industrial medical officer had an important function to perform in the general supervision of conditions of work and measures designed to prevent ill health and injury, in the initial treatment of accidents, and the follow-up of cases that can stay at work and of those who returned after treatment and rehabilitation. He is the one person who can interpret the wishes of the surgeon because of his knowledge of the conditions of work and the types of job available. There must be a steady improvement in the initial treatment of injuries. The sepsis-rate was high and insufficient care was taken of so-called minor injuries. In 1000 consecutive accidents in one factory 52% were finger injuries only; the incapacity-rate was large because they were not treated with the seriousness due to them One big problem was to provide an adequate service for the treatment of injuries in small factories which could not have their own medical units In Birmingham they had proposed the provision of a travelling surgical unit, thus taking the hospital to the factory for the more serious injuries which should be dealt with in the initial stage on the spot (One such unit provided by the Austin Motor Company was demonstrated for the meeting)

Mr J L Smyth, for the trade unions, felt that more should be done to prevent accidents by ensuring proper selection of personnel so that people did not work on jobs for which they were unfitted He made a plea for a greater understanding of each other's job as between the doctor and the workman The ignorance of the doctor about working conditions was often responsible for much misunderstanding, particularly as it referred to certification under the Workmen's Compensation Act At the same time the workman often misunderstood the doctor's position The industrial doctor may be handicapped because he is himself an employee of the firm His job, however, was to serve the workers, and probably he would himself prefer to be independent altogether of the management He deprecated the controversies arising in the courts between the individual worker and employer, with lawyers and doctors ranged on either side to fight the matter out The trade unions were delighted to have been associated with the development of the idea of rehabilitation centres such as had been outlined by Mr Watson Jones Those centres already in existence had furnished practical demonstration of their value The Trade Union Congress had approved of the idea and called on its general council to demand the Minister of Health to bring about an intensive development of this service, which would include mobile medical units The compensation bogy must be destroyed He would like to see standardised records at all hospitals and the preservation of continuity of treatment

In the discussion, Sir Walter Citrine remarked on the big element of conservatism to be overcome both on the part of doctors and workmen There was no place for the consideration of economic motives Their noblest aspiration should be by skill and organisation, whether in hospital or rehabilitation centre, to take away the disability produced by accident Trade unions were willing to cooperate with anyone, whether employers or social agencies, if they were imbued with those ideals

Mr George Perkins, FRCS, of Roehampton, emphasised the need for starting the work of reconditioning from the initiation of treatment in hospital and that the work should be throughout supervised both in hospital and centre by the surgeon in charge of the case

Mr R Watson Jones, FRCS, of Liverpool, said it was just as important to avoid the fear and litigious atmosphere that may develop after injury as to avoid non-union of a fracture Every fracture surgeon must be more than a craftsman, he must be a psychologist The newness of the idea of rehabilitation is only in putting forward the psychological aspect so prominently Rehabilitation centres must not be a counterpart of the old massage departments of hospitals They must be geographically separate, with the advantages of open air, freedom and separation from the hospital atmosphere The problem was far more than economic or humanitarian, it was vital in war-time that every man should be back at work

The President emphasised the important part played by Sir Robert Jones in the development of rehabilitation It was he who in the last war had urged the value of active cooperation of mind and limb in the restoration of movement in stiff joints and in the restoration of muscle power and coordination At the workshops at Shepherd's Bush he showed what could be done for the reconditioning of the disabled The tragedy was that much of his teaching in this direction had been allowed to slide

Reviews of Books

Obstetrics

Oxford Medical Outline Series Hervey Clock Williamson, MD, FACS, associate clinical professor of obstetrics, gynecology at Cornell University Medical College, George Schaefer, MD, assistant attending surgeon in gynecology clinic of St Luke's Hospital London Humphrey Milford, Oxford University Press *Pp 113 12s 6d*

This small volume does not pretend to be a textbook of obstetrics it is just a synopsis of practical lectures, set out in telegraphic style Controversy and hypothesis have been rigorously pruned out, bald facts are presented as a series of tabulated headings The result is concise and quickly readable, covering almost every aspect of modern obstetric teaching English students may find the details but not the fundamental principles of the text a little different from the home product, and this will do them no harm Between each page there is a blank leaf for notes and diagrams—useful in a book which is not illustrated It should prove of value for revision on the eve of the finals

Vision a Study of its Basis

S Howard Bartley, Washington University School of Medicine London Macmillan Pp 350 *18s*

A book on vision which does not describe the refractive system of the eye and gives theories of colour perception the cold shoulder is worth a second glance Dr Bartley's monograph contains almost nothing usually taught to medical students, but much which investigators are known to have been studying during the last dozen years It has been written in the missionary spirit, to tell workers in other fields what modern problems of vision are and how they are being attacked by the experimental psychologist and physiologist—particularly the so-called electrophysiologist It also throws out a hint to the neurophysiologist that the secret of cortical activity may not yield to the infinite exploration of neural elements and their interactions In vision the retinal image and the mosaic of receptors appear superficially to have an obvious relationship, yet striking predictions of experimental results have been made on a theory which relates stimulated points not on an anatomical basis but according to the [illegible] and direction of hypothetical visual field forces somewhat analogous in conception to gravitational and magnetic forces This idea—revolutionary to most of us in this connexion—occupies only a fraction of the text, but is a sample of some of the challenging thoughts which the book brings to our notice Most of the text is hard experimental fact It is a book for which many have been waiting, but many will continue to wait because (except where personal interest fires his exposition) the author is not lucid, and much of his English is frankly bad This is a pity, for, while some part of the book will be familiar ground to any specialist, few will possess such specialised knowledge as to enable them to read the whole without difficulty A little more sympathy with the reader would have made all the difference, as an encouragement to the persevering it may be said that in general it improves as it goes on

Surgery of the Ambulatory Patient

L Kraeer Ferguson, MD, FACS, assistant professor of surgery, University of Pennsylvania London J B Lippincott Pp 923 *63s*

This book covers far more than minor surgery, as usually understood Dr Ferguson, writing from personal experience, makes a strong case for ambulatory treatment of many conditions which in this country would be treated with the patient in bed Descriptions of pathology, diagnosis and differential diagnosis are as full and clear as those of the surgical procedures advocated A section on fractures by Dr Louis Kaplan is particularly good The work contains 645 illustrations, all of them apposite and well reproduced Under the American system, surgeons work in office buildings which probably lend themselves more readily to efficient surgery on the ambulatory patient than do English consulting-rooms Possibly the American patient is more stoical and cooperative than his English counterpart

---

Messrs H K Lewis have published a supplement giving the names of the books which have been added to their library, up to the end of 1941, since the last complete catalogue was issued in 1937 The list of books is arranged alphabetically under the names of authors and there is also a classified index of subjects at the end The supplement is on sale to subscribers to the library at *2s*, but as a guide to current literature on medicine and allied subjects many others will find it worth the *4s* which is charged to outsiders

THE LANCET

LONDON SATURDAY, OCTOBER 17, 1942

IMMERSION FOOT

THE ill effects of chilling on the feet of soldiers has been recognised in many wars There is a good description by LARREY from Napoleon's Russian campaign of 1812, and other accounts in the records of the Crimean war (1854–56) and Russo-Japanese war (1904–05) In 1914–18 many soldiers, especially in Flanders but also elsewhere, suffered from trench foot, which GRATTAN[1] in the official medical history likened to a large chilblain, and LORRAIN SMITH, RITCHIE and DAWSON[2] clearly differentiated from true frostbite Hitherto the published cases have mainly been in soldiers, and the world war now raging may yet provide additional experience in our armies So far, however, in this war the problem has arisen almost entirely in sailors, and it will be strange if some medical writings concerning them are not discovered from former days Ships are torpedoed and sunk far from land and survivors are immersed while clinging to wreckage for many hours, or are huddled together, soaked and cold, in rafts or life-boats for many days These happenings have provided a considerable experience of the effects of cold on the feet in men of the Royal Navy and Merchant Navy, as described by UNGLEY in our present issue

The nomenclature, as UNGLEY points out, is unsatisfactory Among our sailors the condition has become known as immersion foot, or (less commonly) lifeboat leg, but it may occur when feet are not immersed and the men not in lifeboats The hands too and even the nose may be affected in a similar way The same difficulty arose in the last war about trench foot, trench fever and trench nephritis (later changed to war nephritis), none of which were confined to the trenches UNGLEY suggests the term "vasoneuropathy after chilling," based on the probable pathology of the condition he has seen in sailors, but it seems wise for the present to keep to the commonly used terms. The incidence of immersion foot has been mainly in northern waters with a sea temperature of 15° C or below—often below 10° C, but above freezing-point In its full-fledged state the condition is seen rarely, if at all, in survivors exposed in the warmer seas There has been difficulty and confusion in distinguishing between the effects of actual freezing of the tissues (genuine frostbite) and the effects of prolonged chilling at temperatures above freezing-point Clearly trench foot in soldiers (although often called trench frostbite) and immersion foot in sailors both fall into the second category Genuine frostbite has been seen by UNGLEY in sailors during this war—in the fingers when holding on to frozen rigging and in the knees after bailing in ice-coated life-boats Frostbite of the foot has probably not occurred in sailors, and in UNGLEY's two cases in which the fingers and knees were frostbitten the feet showed the typical phenomena due to immersion in water The distinction is important since the two conditions—immersion foot (or hand) and frostbite—contrast strongly in the time of exposure, in their pathology and in measures for prophylaxis and treatment It is obviously desirable to obtain material from early essential amputations for severe immersion foot, so that the pathology may be studied before any later effects of gangrene or sepsis have supervened BLACKBURN, in UNGLEY's paper, describes the changes in vessels and nerves found in late cases of amputation, which alone have been available

In attempts to elucidate the pathology of trench foot LORRAIN SMITH, RITCHIE and DAWSON carried out experiments on rabbits, in which a condition clinically very similar to the soldier's foot was easily induced They noted that the chief effect was on the blood-vessels, whereas the nerves showed only œdematous swelling of axis cylinders (which they regarded as part of the general œdema of the foot) with no degenerative changes In immersion foot the neuritic manifestations seem as a rule to be more severe and the resulting disability far longer lasting than in trench foot but only careful pathological study and experiment can clear up this point and explain the mechanism of the nerve damage BRUCE[3] drew attention to the frequency of fulminating tetanus in trench foot of soldiers, and prophylactic injection was ordered even when the skin was intact This complication has not been seen in immersion foot Complete gangrene of an immersion foot is uncommon, but unfortunately does occur Far more often, as UNGLEY emphasises the loss of tissue is superficial and even if the whole foot becomes black deep tissue loss may involve only the toes or parts of them The main problem of immersion foot is the long incapacity that so often results, already lasting in some cases for over two years

NEW OUTLOOK ON TUBERCULOSIS

THE publication last week of the Medical Research Council's report on tuberculosis in war-time gives us an opportunity to review the present trend of opinion on this hydra-headed disease and especially to study why, despite all improvements in diagnosis and therapy, early recognition and arrest of disease are still the exception rather than the rule In the days when the stethoscope ruled it was often difficult to make an early diagnosis, and the wise physician when in doubt would describe the patient as "threatened" with tuberculosis Modern X-ray technique enables us to see infiltrations unaccompanied by obvious symptoms and still less commonly by physical signs Although the detection of tubercle bacilli in the sputum is more precise than any other method of diagnosis, the early case usually has no sputum and the diagnosis is mainly radiological, often a definite opinion can be given on a single film, but in difficult cases a second or a series of films may be required before a confident statement can be made In some cases, particularly in routine periodic mass radiography, minute opacities appear and subsequently disappear in the course of a few months without any definite diagnosis being possible It might be thought that these conditions would have led to over-diagnosis, and it is therefore disturbing to find, as Wing-Commander TRAIL pointed out in our last issue, that the proportion of early TB+ cases (B 1) to moderately advanced and advanced (B 2 and B 3) in the LCC area remains almost constant at 6% to 80% for the decade 1927–37 Trail gives the reason for diagnosis, doctor and patient must meet" But it is now generally recognised that radiological changes usually come before symptoms, and there is no answer to the MRC committee's statement that "in order to discover the disease before symptoms develop the initiative of the X-ray examination must pass from the patient to the doctor. This can be effected only by mass radiography."

---

[1] Grattan H W History of the Great War Medical Services Surgery of the War 1922 vol I p 169

[2] Lorrain Smith J, Ritchie J and Dawson, J *Lancet*, 1915 ii 595

[3] Bruce D *Brit med J* 1917, i, 48

The recommendations of the MRC committee are being acted on promptly by the Ministry of Health, and we are promised 30 units ready for use in a few months' time, each capable of doing 1000 miniatures a day. The committee suggest that these should be used in the first place in industries employing a large proportion of young workers, and also for nurses, medical students and merchant seamen. The superiority of radiological over clinical examination is well illustrated in Trail's survey which covered 30,130 young airmen of whom 0.22% had active and 0.36% inactive lesions; these men, it should be noted, formed a selected group as they had all passed a thorough clinical examination without the disease being detected. He estimates that in Great Britain among the supposedly healthy young adult population between 18 and 24 there are some 3 per 1000 with unsuspected active tuberculosis, making a total of about 15,000 in all. This observation throws doubt on the conclusions of the Horder Committee which state that the present system of medical examination of recruits reduces the number of cases of tuberculosis accepted by the Forces to an almost negligible figure. Fears have been expressed that the wide use of mass radiography will result in increased shortage of labour in factories engaged on important war work; it was the experience of Messrs Philips at Eindhoven that adoption of mass radiography was soon followed by so great a fall in absenteeism due to tuberculosis that the cost of the scheme was more than made up by the increased number of hours worked. It has also been objected against this method for detecting early cases that beds for tuberculous patients are already inadequate. A temporary increase of cases requiring treatment would be inevitable, but early diagnosis reduces the number of months of sanatorium treatment and should soon reduce the numbers of chronic cases needing institutional treatment. In any case, the shortage of nursing and domestic staff in sanatoriums, which now forms a serious handicap to the treatment of tuberculosis, must be faced.

The MRC committee have produced a report which should be widely read both inside and outside the profession. The probable causes of the increase of tuberculosis are discussed in detail, and the differences in the age-group incidence between this war and the last are examined. From this it may be concluded that although the evacuation of town children to rural areas where unpasteurised milk is drunk must have caused some increase in bovine tubercle the bulk of the increase is due to the human bacillus though how much is caused by increased infection under blackout and shelter conditions and how much by industrial fatigue and the strain of bombing cannot yet be determined. A recent paper[1] on tuberculosis in London in war-time shows that in this heavily bombed area the pulmonary tuberculosis death-rate has increased by 72% and the non-pulmonary by 67%, these increases being much greater than those found in the rest of the country; children were more affected than adults but there is evidence that pasteurisation has limited bovine infections and that the principal infecting source is human. Another thought-provoking report is that of the Prophit Survey of the Royal College of Physicians, summarised on p. 463; tuberculosis in young adults has been closely studied, especially by correlating Mantoux tests with X-ray examinations. The preliminary analysis shows that an appreciable proportion of young adults are now tuberculin negative, the figures for negative reactions among nursing entrants being 11.5 for voluntary hospitals and 17.8 for municipal. The survey was started in 1934 but was interrupted by the war. Their figures suggest that there is a useful correlation between the tuberculosis reactions and the development of tuberculous lesions, but before publishing them it was thought advisable to extend the period of observation.

The relative failure of treatment in pulmonary cases is naturally largely due to the rarity of early diagnosis; but this is by no means the whole story, since many cases which should have a good prognosis die from the disease. Tuberculosis mortality has been described as a social barometer. Probably the great fall in the incidence of the disease during the last two generations has been due more to improvement in the standard of living than to the work, good as it has been, of dispensaries and sanatoriums. The weak spot on the treatment side is the period following discharge from sanatorium; few patients at this stage can safely return to full-time work under ordinary industrial conditions, and they require plenty of good food and satisfactory housing conditions. At present, as Heaf and Rusby[2] have calculated, allowances from public funds for the tuberculous patient who is unfit for work are so meagre that if the whole amount is spent on food only just enough to meet his requirements can be purchased. The patient with quiescent disease steers a perilous course between the Scylla of underfeeding and the Charybdis of overwork. The MRC committee's case for the introduction of satisfactory methods of industrial rehabilitation is in fact unanswerable. The financial position of the worker drawing NHI disablement benefit of 10*s* 6*d* a week without allowance to his family is contrasted with that of the soldier disabled by tuberculosis who receives 37*s* 6*d* a week plus 9*s* 2*d* for wife, 7*s* 1*d* for first child and 5*s* 5*d* for each other child—yet the need is the same. Among the recommendations made for the rehabilitation of convalescent non-infective cases are part-time work and "modified" work—that is, work under less strenuous conditions than usual—in each case the wages earned being subsidised from national funds in order to ensure an adequate standard of living.

Mass radiography cannot be used extensively in diagnosis unless the economic penalty now attached to tuberculosis is removed; while it exists adequate cooperation from the workers cannot be expected. The Minister's announcement on Oct. 8 that local authorities have been authorised to grant financial assistance while the breadwinner is undergoing sanatorium treatment is of happy augury. If the Government would go one step further and announce pensions for chronic cases and subsidised wages during rehabilitation, the spectre of want could be banished from the tuberculous population.

ELECTROENCEPHALOGRAM IN WITNESS-BOX

At a general court martial last winter a soldier who had fired a rifle at a corporal pleaded that he had no knowledge of the affair but had suffered a head injury a few hours before the alleged time of the incident. No-one had witnessed the injury, and there was little clinical evidence to support the plea, except that the attack was without motive, unpremeditated, and was followed by singularly apathetic behaviour. An electroencephalogram showed abnormal changes compatible with a head injury of the severity described by the prisoner, and the abnormalities subsided in a couple of weeks. This evidence was accepted and the man was discharged. On July 14, a man was tried at the Winchester Assizes for a singularly brutal and seemingly purposeless murder. The defence was that the act was committed in a period of postepileptic confusion. Expert medical opinion supported this view on the evidence available, some of which was tenuous. Evidence was produced that the man had an abnormal EEG and that the changes seen after over-breathing were epileptic in character. It was pointed out that although an absolute diagnosis of epilepsy could not be made on the EEG alone, since no subclinical attacks were seen, the presence of such a record in a man who had behaviour suspicious of epilepsy made that diagnosis very likely indeed. The prisoner was found guilty of murder but insane. A correspondent in the *Times* of Sept 16 suggests that the verdict might well have been different if the EEG had not been before the court. Since these two cases, similar evidence has several times been called elsewhere, and it has been accepted in courts of law in the United States for some time past.

The electroencephalogram does not show characteristic changes in every case of epilepsy, and in only a minority of epileptics are true subclinical attacks seen. Furthermore the relatives of epileptics, themselves apparently normal, may show similar abnormalities,[1] and unstable people, including psychopaths,[2] criminal delinquents and even constitutionally predisposed neurotics,[3] are liable to have an abnormal EEG. HILL[4] has pointed out that since it may reasonably be assumed that a high proportion of murderers have unstable temperaments and are consequently likely to have an abnormal EEG, the value of the test is reduced, since a diagnosis of psychopathic personality is no defence in law. He therefore rightly urges the most conservative use of the method. It is true that the EEG provides proof positive of epilepsy in only a small proportion of epileptics, and that some have quite normal records, but in the cases cited it was used, and accepted by the court, as corroborative evidence. In clinical medicine it is rare, perhaps unknown, to find a test which is infallible, but this does not prevent these tests being used to add to clinical knowledge. In the court of law a final opinion as to fact is reached by question and answer in much the same way as in medicine, and in the end it is not an infallible opinion, but only one which may be accepted beyond all reasonable doubt. Thus radiology and serology, with all their pitfalls, are called to add to the sum total of knowledge which is used to achieve justice. The limitations of the EEG are sufficiently understood for it to be used in the same way. Its sphere of usefulness includes behaviour disturbances of all sorts, the epilepsies and the abnormal states which accompany them, as well as the less clear cut disorders of psychopathic adults and delinquent children,[5] and of psychotics. It has been accepted as corroborative evidence of a head injury, and no doubt will often be used in compensation cases. Now that it has been shown to have forensic value, its application should be guarded, lest it be abused. There are few instruments in the country, and still fewer operators competent to give an opinion in a court of law. Given the apparatus it is easy to obtain a record, and one who gives an opinion has few to criticise him, so that the method presents a fertile field for the unscrupulous. Knowledge of the clinical interpretation of results is advancing steadily, and the method is now incorporated into the routine investigation of several disorders, but until recently it has been used mainly for research purposes, and has been absorbed into the clinical sphere with commendable discretion. Now that it has been brought to the public notice in courts of law steps should be taken to safeguard its use.

It is perhaps an over-simplification to suggest that men have been hanged for the lack of an EEG. Insanity for the purpose of determining criminal responsibility in an assize court is notoriously different from insanity as seen and studied by the medical man. Many people are convicted of murder whom medical witnesses regard as insane. The official statistics, however, provide material for believing that defences of insanity which fail to avert a conviction for murder are nevertheless often sufficient to save a man from capital punishment. The trial of Ronald True in 1922 for the murder of Gertrude Yates illustrated the sharp division between the legal and the medical standard. True was convicted of murder but, after further medical inquiry, was respited and sent to Broadmoor. The law-courts accept the fact that epileptic murderers are known to medical science. The symptoms of epilepsy in the case of True were slight—little more than sudden lapses in conversation and memory. NORWOOD EAST, giving evidence on his behalf, explained the two kinds of epilepsy from which True might have suffered—epileptic mania or fury, a wild condition of excitement lasting a short time and leaving no recollection of what had happened, and epileptic automatism where also the patient would have no subsequent recollection. Mr Justice MCCARDIE put the point carefully to the jury. If True killed Gertrude Yates while in an actual epileptic seizure, then, even though he knew the physical nature of the act and also that it was morally wrong and punishable by law, the jury ought to return the verdict of "guilty but insane." True's mental instability was ascribed to other causes than epilepsy. Here an EEG might have thrown light on the diagnosis, but the real obstacle in all these cases is that the machine may contribute proof of a specific dysrhythmia from which conclusions may be drawn, but it cannot tell the jury the state of a man's mind at a particular moment in the past. It does not prove sanity or insanity for the purposes of judge and jury. By itself it cannot establish automatism on some past date, it cannot declare a man's consciousness or intentions at some moment two months ago. That missing evidence is what the courts require.

Annotations

DOSAGE OF VITAMIN D

THERE is no certainty about how much vitamin D children need A League of Nations commission in 1938 put the requirements of infants at 400–500 IU daily, and President Roosevelt's National Nutrition Conference last year endorsed a figure of 400–800 IU daily for either infants or children up to 15 years but higher estimates have been made A subcommittee of the British Pædiatric Association, consisting of Dr Wilfred Sheldon, Dr Charles Harris, Prof Noah Morris and Dr Helen Mackay, have summarised present views and tried to establish some working instructions for mothers They say that although a daily intake of 500 IU would probably protect most full term infants and young children from rickets a daily allowance of 700 IU would give a wider margin of safety The cod-liver oil compound now supplied by the Government for children under 5 years contains " not less than 100 IU of vitamin D per gramme," and the dose recommended rises from half a teaspoonful for babies under 6 months to a teaspoonful, thus providing some 200–400 IU daily, a dosage which the subcommittee consider inadequate They also disagree with the advice to give babies under 6 months less than older babies, for the incidence of rickets is as great under as over 6 months, and in view of the more active growth in the earlier months the prophylactic requirement of vitamin D is greater then . They advise that vitaminised oil for distribution to children should be reinforced with irradiated ergosterol so that a teaspoonful will contain the daily allowance of 700 IU, as well as the present 3500 IU of vitamin A Mothers should then be told to begin by giving the baby a few drops of this oil daily when a month old, and work up to a teaspoonful daily in a fortnight This applies whether the baby is on breast or bottle The premature infant (birth-weight under 5½ lb) requires something like twice as much vitamin D as the full time infant, so that the mother should give these underweights two teaspoonfuls of the oil, or 1400 IU daily, divided into four equal doses, this should be continued summer and winter Babies whose birth weight was over 5½ lb need not be given vitamin D in summer provided they are suitably exposed to sun and skyshine for at least four hours daily The subcommittee advise the same dose of 700 IU daily for older children on a mixed diet, dropping to 3500 IU a week at school age, when it might be issued with the school milk or school dinners Pregnant and nursing mothers should also receive a supplement of 700 IU daily, and this will not take the place of the supplement for breast fed babies Finally, the subcommittee suggest that for the information of doctors the composition and vitamin content of cod-liver oil compound should be given on the label, they might have added that a similar statement should appear on all vitamin preparations

CONTROL OF THE TYPHOID CARRIER

THE chronic carrier is the most important factor in the maintenance of endemic typhoid and paratyphoid infection and is often the source of epidemic outbreaks Typhoid, though now rare in this country, is still responsible for much morbidity and mortality in America and in many subtropical countries, here it is being supplanted by paratyphoid, of which there has been an increased prevalence in recent years and often in a form so mild or atypical as to be clinically unrecognisable The control or cure of the carrier is therefore essential if these diseases are to be eradicated After an acute attack of typhoid or paratyphoid, many patients continue to excrete the pathogen for weeks after they are clinically well Persistent convalescent and chronic carriers are most often elderly married women—for example, in the 1941 Liverpool outbreak,[1] of 16 (out of 339) cases who continued to excrete the paratyphoid bacillus for more than 16 weeks after infection, one was a man aged 52, 2 were young children and 13 were women, 9 of them over 40 years of age A carrier is arbitrarily classified as a chronic carrier if excretion continues for more than a year, and it is estimated that 2–4% of clinical cases become chronic carriers, but a chronic carrier state may develop in a person who has never had a clinical attack

The gall bladder is the focus of infection in most enteric carriers, and cholecystectomy has so far been the only reliable method of cure In two collected series,[2 3] 75% and 77% of the operated cases were permanently cured, and no doubt these results could be bettered It is important to know that cure may result though the patient goes on excreting the pathogen by drainage tube or in fæces for weeks or even months after cholecystectomy But even with improved surgery and anæsthesia the operative risk on a stout, elderly woman is not negligible, and of course many carriers will refuse the operation, so that alternative methods of control or cure must be sought The carrier can by law be forbidden employment in any trade or business concerned with the preparation or handling of food or drink for human consumption, but apart from this legal restriction, plus education in personal hygiene, control is not easy, and the carrier, as in the famous case of Typhoid Mary,[4] may readily evade the restriction Isolation, except in institutional cases, is not permissible in England, although in Scotland the local authority has the power to deal with a person adjudged to be a carrier of an infectious disease as though the person actually suffered from the infection

While many carriers remain apparently well, some have the symptoms of gall-bladder disease, and most of them, if untreated, experience a sense of contamination which has sometimes led to mental breakdown Any *medical* treatment, therefore, which offered any prospect of cure would be welcomed by these sufferers In the past such treatments as chemotherapy, physiotherapy, bacteriophage, vaccines and alteration of the intestinal flora have consistently failed to cure[2] Lately various sulphonamides (sulphapyridine,[5] sulphasuxidine,[6] sulphaguanidine and sulphadiazine[7]), and mepacrine[8] have been tried without success, but claims have been made for the soluble tetraiodophthalein which is used for X ray visualisation of the gall bladder In the United States Saphir, Baer and Plotke[9] treated 65 biliary carriers in a mental institution with intensive dosage of iodophthalein, they gave 4 g doses by mouth three times a week with the patients on a low fat diet, the drug being taken in the morning so as to get maximum concentration and retention in the gall-bladder during the night There were no ill effects, apart from some nausea and occasional diarrhœa Of the 65 treated patients, 21 (32 3%) gave three consecutive negative cultures of duodenal contents but in only 5 of them did the stools become persistently negative It seems unlikely that the remaining 16 cases had intestinal foci in addition to that in the gall bladder, more likely duodenal aspiration was failing to recover gall bladder bile It is significant that in the cured cases visualisation of the gall bladder was good, and attempts at cure by this or allied substances probably require a gall-bladder in which the drug will be retained

and concentrated Although the results obtained by Saphir have not been confirmed by other workers they are sufficiently encouraging to warrant further research along this line It is suggested that for elderly patients iodophthalein should always be tried before surgical intervention, and the drug might be useful in hastening cure of the convalescent carrier

SOAP FOR THE CUT HAND

This is a war of production and with our limited man power any wastage due to the minor injury is serious According to Stewart[1] over 11% and probably up to 20% of minor injuries in which compensation for over 3 days incapacity has to be paid are due to sepsis In a consecutive series of 1000 cases that attended a factory surgery over half came because of hand injuries The treatment of such injuries is often unsatisfactory and usually consists of a perfunctory iodine dab without preliminary cleaning Kerrigan[2] aware of the obvious failing of the workman's hand 5 years ago started using soap and water only for cleaning such wounds Writing of his experience in Michigan City, a big lumber centre he assures us that not a single case out of 9105 compound hand injuries where attention was given within the first few hours required admission to hospital the 10 cases which were admitted first attended one or more days after the accident Some cases did develop minor infection but with suitable splintage all were able to continue at their work under careful observation Kerrigan prefers a neutral white soap which is applied with cotton wool swabs and also uses benzene or ether to clean the surrounding stained greased skin of the workman But he points out that for the severe injury careful wound excision is still absolutely necessary In this series no sulphonamides or other forms of chemotherapy were employed A neutral soap is not essential and indeed Colebrook[3] has shown that yellow household soap has a bactericidal power superior to refined soap This bactericidal power is greater in warm water, and 5 minutes washing in 3 or 4 pints of water will destroy most of the pathogens commonly met with in sepsis Early attention to the cut hand by soap soaks and washing should be taught to the factory staff The bandage soiled at work later forms a path for infection so there is still need for some waterproof cover if the workman is to go on with his job and the best form of rehabilitation treatment for the injured hand is often a man's ordinary work.

THE STREPTOCOCCUS IN ACUTE RHEUMATISM

SINCE the pioneer researches of Poynton and Paine at the beginning of the century the part played by streptococci in the ætiology of acute rheumatism has developed into a major problem Much of the earlier work had for its object the isolation of microbes from the fluids or tissues of cases of acute rheumatism, and on the infrequent occasions that cultures were obtained they were mostly of non-hæmolytic streptococci, particularly *Streptococcus viridans* these organisms were therefore formerly regarded as the most likely candidates for the ætiological rôle During the past ten years, however largely as a result of the epidemiological studies of Coburn, hæmolytic streptococci have seemed increasingly important The application to this field of the refinements in bacteriological technique introduced by Todd, Lancefield and Griffith has resulted in an extensive literature which has recently been surveyed by Green[4] Bacteriological studies have demonstrated an epidemiological relationship between hæmolytic streptococcal infection of the throat and the incidence of acute rheumatism Apart from clinical infections, a high carrier-rate for hæmolytic streptococci has also been observed in rheumatic subjects thus Green found group A streptococci in 50 5% of rheumatic throats compared with 12 5% of the throats of normal controls In individual cases of rheumatic fever too, relapse is often accompanied by the reappearance or an increase in the numbers of hæmolytic streptococci in the throat The proportion of individuals displaying skin sensitivity to the injection of streptococcal extracts has been found to be considerably higher in rheumatic subjects than in normal controls Green found while this sensitivity was not specific for any one kind of streptococcus it occurred more often when the extracts were from hæmolytic streptococci It should be noted that these observations apply to extracts of bacterial bodies—'endotoxins'—and not to streptococcal exotoxins Since the demonstration by Todd of the antigenic nature of streptococcal hæmolysin and of the practicability of measuring the corresponding antibody titre in human serum it has been established that these anti-streptolysin titres show a well marked rise after infections with hæmolytic streptococci several workers have found that anti-streptolysin titres are also significantly raised in many cases of acute rheumatism Green points out however that recrudescence of the disease does not necessarily result in further increase in titre While attempts to isolate hæmolytic streptococci from joint fluids have been seldom successful, Green recovered these organisms from the heart valves at autopsy in 8 of 9 cases of acute rheumatic carditis Thomson and Innes repeating this work were also successful in 5 cases out of 10 Green considers that the available data support Coburn's contention that the rheumatic state results from an abnormal response to a hæmolytic streptococcal infection leading to sensitisation of the tissues, on coming into contact with further supplies of the antigen the sensitised tissue may then react by producing the characteristic lesions of rheumatic fever Recent work also lends support to the view that heredity is an important predisposing factor

MECHANICAL CONTROL OF COLOSTOMIES

MANY ingenious operations have been devised to give mechanical control of the bowel in cases of permanent colostomy These have included the use of specially designed obturators, the fashioning of the artificial anus in such a way that the stoma finally becomes very small and can be corked, insertion of the proximal limb of the colon through a specially constructed muscular ring and implantation of this limb through a subcutaneous tunnel None of these has been popular in England, though they are practised in France Italy, Germany and some Latin American countries R B Gonzalez of Venezuela[1] has modified Cuneo's[2] operation and reports favourable results in 21 out of 26 cases His aim was to secure true continence and not merely regularity of the bowel by means of dieting and colonic lavage In his operation the exteriorised functioning limb of intestine is closed by a compression device Two parallel horizontal incisions are made in the left iliac fossa and carried down to the external oblique aponeurosis, the oblong area of skin thus outlined is made into a tube by stitching the two edges to one another The upper edge of the wound is undermined and the peritoneum is exposed and opened A loop of sigmoid is drawn through the wound and divided with a cautery between two enterotomes, the lower end is invaginated and returned to the abdomen The peritoneum is sutured round the upper limb of colon and the muscular layers are closed round it without compression The limb of bowel is then carried across the skin tunnel and brought out through the lower flap of the original wound The upper and lower skin flaps are then united in a bridge over the limb of colon, which thus lies between the skin superficially and the skin tunnel deeply The cut end of the bowel, still secured by a clamp, is fixed by a few sutures to the small circular skin incision, the clamp is left on for 24–48 hours, and when it is removed pains are taken to avoid soiling the wound by fixing rubber sheeting around it When all is healed the compression device, a special forceps shaped somewhat like a safety-pin, can be used One arm of this is passed beneath the bowel through the skin tunnel and the other above it, the two arms being fastened together, by means of a bolt and nut, tightly enough to maintain continence without producing pressure necrosis of the entrapped portion of bowel Dilators are used for some weeks after operation to keep the skin tunnel from contracting unduly Of Gonzalez's 26 patients, 1 died from peritonitis, 2 developed pressure gangrene of the loop and lost the skin tunnel, 2 had a fairly severe ventral hernia, and in the remainder the result was apparently satisfactory The operation shows great ingenuity, and is comparatively easy to perform, but it obviously cannot be done if there is much stenosis of the rectum or lower sigmoid, because the invaginated loop of bowel distends and may rupture, it is contra-indicated in carcinoma of the rectum or lower reaches of the sigmoid, nor is it suitable, as Gonzalez himself points out, in cases of diverticulitis because the sigmoid is often fibrotic, and it is too long an operation to be borne by any patient who is seriously ill Again, results may be complicated by peritonitis, infection of the wound, distortion or stenosis of the tunnel, ventral hernia or cellulitis, and finally unless the safety-pin device is adjusted by an intelligent person the compressed portion of the gut may become œdematous or even gangrenous In England, then, indications for this operation are very limited Gonzalez operated chiefly on cases with lymphogranuloma venereum of the rectum or lower sigmoid, and for such patients it may have a place The condition is rare in Britain, but in any case most surgeons here would probably prefer to treat it palliatively with graduated rectal dilatation, mild local disinfectants and sulphathiazole both locally and by mouth If colostomy was necessary probably most would favour loop colostomy, or the defunctioning type of colostomy devised by Devine

LIVER NECROSIS AFTER BURNS

Necessity, the mother of invention, is sometimes too importunate in her choice of mate to be critical, the offspring may then develop blemishes that betray the hasty marriage The therapeutic problem of burns was immense, when therefore tannic acid treatment was first introduced by Davidson in 1925 and the immediately satisfactory results had been widely confirmed there was little room for criticism Later critics have in general confined themselves to saying that tannic acid should not be used on this or that part of the body, or that better tanning was produced by other agents such as silver nitrate or triple dye or by combinations with antiseptics and bacteriostatics Only of late, with the general reawakening of interest in the investigation and treatment of injuries, have the effects of tannic acid treatment been more closely re-examined The fact that liver necrosis in burns [1] has become widely recognised only since tannic acid therapy was introduced might be related merely to the longer survival of severely injured patients The majority of such used to die from plasma loss on the first day, but surface coagulation and serum transfusion have considerably decreased the mortality from this cause That the liver necrosis might to due to therapy is an alternative possibility It seems unlikely that the plasma or serum would be to blame, since the infective jaundice recently found to be transmitted by serum (whether given for mumps, for yellow fever prophylaxis or for other reasons) has an incubation period of several weeks The remaining possibility, that the liver damage might be due to tannic acid, has been investigated by Wells, Humphrey and Coll [2] They detail and illustrate well-marked liver damage in rats, rabbits and guineapigs after subcutaneous injection of tannic acid The damage was proportional to the amount injected These results, if confirmed, would not necessarily mean the abandonment of what has proved a highly effective mode of treatment, but they would call for an attempt either to inhibit this harmful effect or to find some other coagulative agent with less undesirable side actions

IMPACTION OF THE EPIGLOTTIS

Lately Caiger [3] of Durban, South Africa, has drawn attention to the possibility that impaction of the epiglottis in the larynx may obstruct breathing during anæsthesia Caiger's view is that if muscular relaxation allows the epiglottis to fall back sufficiently for the inspired air to impinge on its anterior surface the air may force the free part of the epiglottis through the glottis He has met with half a dozen cases of such impaction, and has relieved it by drawing the tongue forward and lifting the epiglottis with the finger, on one occasion disimpaction produced an audible click The fact that this impaction cannot be produced or demonstrated after death is no certain proof that it does not arise during life, but the size, consistency and position of the normal epiglottis make it difficult to imagine its being blown or sucked into the larynx, for this to happen the epiglottis would have to be unduly pliable Certainly this is not a common cause of obstruction The usual causes of obstructed breathing are well recognised and readily relieved when treated promptly Caiger, however, suggests that swabbing out the pharynx, drawing forward the tongue and artificial respiration may all be effective sometimes because they release an unsuspected impaction His contention that impaction may have been the cause of a considerable proportion of unexplained anæsthetic deaths is unconvincing, for most records of such deaths expressly state that there was no obstruction to breathing All the same, Caiger's suggestion may lead anæsthetists to study with enhanced interest the exact arrangement of the upper air-passages when next they meet with obstructed breathing in anæsthesia

Sir Henry Dale, PRS, has accepted the directorship of the laboratories of the Royal Institution, with the Fullerian professorship, in succession to the late Sir William Bragg His appointment is, at his own request, limited to a period of three years, so that the managers may then be free to consider future policy

Dr Arthur Ellis has been appointed regius professor of medicine in the University of Oxford in succession to Sir Farquhar Buzzard, who is retiring Dr Ellis was director of the medical unit at the London Hospital and held a chair of medicine in the University of London until his appointment six months ago to the scientific staff of the MRC as director of research in industrial medicine

Sir Hugh Lett will deliver the second Moynihan lecture at the University of Leeds on Thursday, Oct 29, at 3 PM He will speak on William Hey and after

Next Tuesday will be available the 21 monographs on the *Control of the Common Fevers* which have been arranged for publication with the help of Dr Robert Cruickshank The unwelcome delay has at all events had the compensating gain of making it possible to include chapters by writers who were then on active service abroad While the book is based on a series of articles which have already appeared in our columns and have been widely appreciated, these have been revised or rewritten and nearly as many others added Particulars will be found on our front cover

TUBERCULOSIS IN YOUNG ADULTS

A PRELIMINARY ANALYSIS OF THE PROPHIT SURVEY

F RIDEHALGH, M B CAMB
PROPHIT SCHOLAR RCP 1934–40 DEPUTY CLINICAL TUBERCULOSIS OFFICER, LEEDS

IN 1934 the Royal College of Physicians of London inaugurated under the terms of the Prophit Bequest a survey scheme with the following objects

1 To determine the level of tuberculous infection by the graduated Mantoux tuberculin test

2 To correlate the results of the Mantoux test with the results of X ray examination of the thorax

3 To determine the value of mass X ray examination as a means of revealing unsuspected pulmonary tuberculosis

4 To assess the possible prognostic significance of the Mantoux test

5 To discover the existence and importance of opportunities for primary tuberculous infection in the population studied

6 To determine the significance of certain abnormal appearances in the chest X ray which are not yet fully understood

This paper is a record of the investigation so far as it was completed in the five years immediately before the outbreak of war and is summarised from a detailed report presented to the College All the statistics have been checked by an expert

METHODS OF THE SURVEY

The persons studied are mostly between the ages of 15 and 25 A few children between 12 and 14 are included and a very few adults between 26 and 30 They are divided into five groups (1) "Volunteer controls"—a group of apparently normal healthy office and factory workers, (2) Contacts of cases of pulmonary tuberculosis, (3) Nurses, (4) Medical students (5) Boys entering Royal Naval training establishments A full medical and family history was taken with details of occupation, hours of work, time of travel to work principal recreations place of birth, other places of residence with dates racial history of parents (English Scots, Irish, Welsh Jewish), size of house, size of household with ages, and known contact with tuberculosis This information was given directly or by questionnaire as was convenient Physical examination was normally done only on contacts or if certain abnormal X-ray findings were present

The tuberculin used for the Mantoux test was the International Standard synthetic medium old tuberculin supplied by the Medical Research Council,[1] dilutions in boric acid borate buffer[2] being made monthly from one batch of tuberculin The initial test with 1 10,000 tuberculin was read after 48–72 hours and repeated with dilutions up to 1 100 if necessary Erythema alone was recorded as a "doubtful" reaction, the minimum "positive" reaction being taken as 2 mm of definite œdema with surrounding erythema With the exception of 69 contacts all tuberculin tests referred to below were performed and read by the writer

Full size X ray films were used throughout Most volunteer controls were X rayed by Mr Ferrier, who used the mobile X ray unit of the Joint Red Cross[3] For contacts the ordinary X ray arrangements of the dispensary were used In all other cases the X rays were done by the appropriate hospital or medical school Despite these diverse sources practically every X ray was of good diagnostic quality All films were interpreted by the same committee of radiological consultants appointed by the College

The Mantoux test and the chest X ray were normally repeated annually on each person in the survey to a maximum of five examinations There was a considerable loss of volunteers in every group, postal follow-up being used to maintain contact so far as possible

Volunteer Control Group

704 males and 839 females aged 15–30 were examined in this group They include employees of insurance and other offices, gas companies, the central departments of the Post Office, and other office and factory workers The proportion of factory workers is small That this control group is not representative of London's average population is shown by the very small proportion coming from overcrowded homes, only three of the families being housed at 2 or more per room

Of the males 5 1% gave a negative Mantoux reaction at the first examination, compared with 9 5% of females, and 85 8% reacted to 1 10 000 tuberculin, compared with 80% These sex differences are statistically significant and indicate an excess of positive reaction among the males, which was found also when comparison was made between separate 3-year age-groups

Of the 110 persons, included in the control group, who had migrated to London from the country within ten years of the examination 18% gave a negative Mantoux reaction compared with 7% of those who had lived in the Greater London area for ten years or more a significant excess

The median level of housing in this group came at the low level of 1 2 persons per room Using this value as dividing line, no evidence was found that the group living at higher densities than this included any larger proportion of positive reactors than the group living at lower densities, but rather the reverse

Radiological lesions suggestive of "adult" pulmonary tuberculosis were found in 13 (0 84%) of the 1543 at the first examination, only 2 (0 13%) of these requiring treatment and only 1 having clinical symptoms of the disease Radiological evidence of healed primary infection—that is to say, calcified lung foci, calcified tracheobronchial glands, or both—was found in 110 (or 7 2%) and of these only 2% gave a negative Mantoux reaction compared with 8% of the radiologically normal and 91% reacted to 1 10,000 tuberculin compared with 82% of the radiologically normal Among all positive reactors 5 6% of males showed calcified lesions compared with 9 4% of females a statistically valid difference No conclusive evidence of any association between the incidence of calcified lesions and age was found

The general distribution of Mantoux reactions in 1015 persons in the control group when re-examined after one year was not much different from the distribution at the first examination, though a slight movement towards the positive end of the scale had occurred Among the males who had lived in Greater London for 10 years or more an increase in tuberculin sensitivity

TABLE I—MANTOUX REACTIONS AT FIRST EXAMINATION

Group	—	No examined	MTT + in dilution of 1 10 000 ** (%)		1 1000 (%)	1 100 (%)	MTT ± (%)	MTT – (%)

MTT = Mantoux tuberculin test

Reaction ** to 1 10 000 tuberculin is one with a disc of œdema 20 mm or more across The single asterisk denotes any reaction less than this was noted in 17–19% according to age and a decrease in 4–8%, only 1 initially positive reactor becoming negative. Among the females an increase in sensitivity was noted in 15–16% according to age, and a decrease in 14–16%, 14 initially positive reactors becoming negative. Re-examination after 2 and 3 years showed similar results. The number of migrants from the country who were re-examined was not large enough to form any conclusion as to change in sensitivity.

Tuberculosis Contacts

The term "contact" is here taken to mean a person who is or has been in contact, in his home, with a case of pulmonary tuberculosis (not necessarily sputum-positive) but who is not known to have himself suffered from clinical tuberculosis at the time of the first examination. The infecting patient is almost invariably a parent or sibling of the contact, and in some instances has died before the first examination of the contact. Contacts aged 12 to 30 were collected by the tuberculosis officers and health visitors of ten metropolitan boroughs, selected only for their willingness to cooperate.

784 contacts, coming from 442 tuberculous families comprising 2349 persons were examined, 379 being males and 405 females. The examination and Mantoux tests on all except 69 of these were carried out by the Prophit scholar. In 69 cases the tests were done under standard conditions and with standard materials by the tuberculosis officer.

The districts from which they were drawn together formed a fair sample of London as a whole as regards housing and vital statistics. The contacts, when compared with the general population of London, showed a significant excess of families of 5 or more persons. There was, however, no significant difference between them and the London census population of 1931 as regards the proportion housed at 2 or more persons per room. For families of 4 persons there was no difference in the overcrowding rate, and in families of 5 or more persons the contacts appeared to be living in much less crowded conditions than the general population.

The proportion giving a negative Mantoux reaction at first examination was only 3·0%, and was significantly lower than among the volunteer control group for each sex, but the distribution of positive reactors according to the strength of the reaction did not differ significantly from the volunteer control group.

At the initial radiological examination 2·4% showed active pulmonary tuberculosis, 2·5% parenchymatous lesions considered to be quiescent, and 17·2% calcified lung nodules, calcified tracheobronchial glands or both. The incidence of healed primary lesions was not significantly different in separate 3-year age-groups of contacts.

Column 4. *Healed Primary Lesions* mean calcified nodules in lung, calcified hilar glands visible in X ray film and present separately or together.

Column 5. *Inactive Pulmonary Tuberculosis* means tuberculous infiltration of lung parenchyma not found to require treatment at the time of diagnosis.

On re-examination of 253 contacts after the lapse of one year, an increase in sensitivity to tuberculin was noted in 22% compared with 17% in the control group, the excess being twice its standard error. A decrease in sensitivity was found in 9% compared with 11% in the control group.

The outstanding practical feature of the examination of contacts is the high incidence of active pulmonary tuberculosis revealed. No active lesions were found in the 180 contacts aged 12–14 nor were any healed parenchymatous lesions (as distinct from calcified nodules and glands) found in this subgroup. The incidence of active pulmonary tuberculosis in male and female contacts aged 15–30 was thus 2·4% and 3·9%, plus 2·7% and 3·9% respectively of healed parenchymatous lesions. The value of at least one X-ray film of adolescent and young adult contacts is thus clear, and it is hoped in a future communication to show that repeated annual X-ray examination is no less important.

Hospital Nurses

These were drawn from five large voluntary teaching hospitals and five large general hospitals under the control of a local authority. In nearly all cases the initial X-ray and Mantoux test were carried out while the probationer was still in the preliminary training school so that the figures give a fair picture of conditions at the start of training. The voluntary and municipal groups of hospitals differ in the degree of known contact with tuberculosis which they afford their nurses. The former admit pulmonary tuberculosis patients only in small numbers, either undiagnosed, or after acute emergencies such as hæmoptysis, or for teaching purposes. The municipal hospitals, up to the outbreak of war, practically all had large tuberculosis wards acting as reservoirs for the sanatoria and as asylums for advanced and dying cases.

953 nurses in voluntary hospitals were examined, of whom 63·2% were English, 7·7% were Irish, 5·3% Welsh, 3·1% Scots and 20·7% of mixed parentage. 523 nurses in municipal hospitals were examined, of whom 43·6% were English, 33·1% were Irish, 10·7% Welsh, 4·4% Scots and 8·2% of mixed parentage. There was considerable excess of Irish and Welsh in the municipal group compared with the voluntary hospital group.

Of the entrants to voluntary hospitals 11·5% gave a negative Mantoux reaction when first tested, the proportions not being significantly different from those for the female control group of the same ages. Of the entrants to municipal hospitals 17·8% were Mantoux negative when first tested, a significantly higher proportion than among either the control group or the voluntary hospital nurses. In each group of nurses a lower proportion reacted to 1:10,000 tuberculin and a higher proportion to 1:1000 or 1:100 than amongst the control group, this being true at all ages and at ages 18–21.

Comparison of the Irish municipal hospital nurses with other nurses in the same hospitals revealed a significant excess of negative reactors, the rate being 25% in the Irish nurses. The other municipal hospital nurses included 14% with negative reactions compared with 9% among the control group, an excess very probably significant (2·6 times the standard error) and perhaps due to the higher proportion of Welsh and other than English nurses included.

The voluntary hospital nurses showed on radiological examination 5·9% with calcified lesions compared with 8·5% of the female control group, this difference being of doubtful significance. The municipal hospital nurses showed no difference from the control group in this respect. No case of active pulmonary tuberculosis was found in the group of voluntary hospital nurses, in which 0·4% of healed parenchymatous lung lesions was found. The municipal hospital nurses showed 0·4% of active tuberculosis and 0·4% of healed parenchymatous lesions.

The proportion of municipal hospital nurses initially negative to tuberculin who after a year in hospital gave a positive reaction was 78%, a significantly greater change than among voluntary hospital nurses (42%), or female controls (22%). Only 1 out of 156 initially positive reactors became negative instead of 4 expected from the control group. Doubtful reactors tended to become positive rather than negative after a year in hospital. Strongly positive reactions became weaker less frequently than amongst the voluntary hospital nurses or controls, and weak positive reactions tended to become stronger more frequently in the municipal group Only one nurse was found to remain negative to tuberculin after three years in a municipal hospital

Medical Students

1247 preclinical medical students were examined, 1106 being males and 141 females They were recruited from seven medical schools of the university of London and from three provincial universities The methods of examination were the same as those used in all other groups and the initial Mantoux test and X ray were carried out in the preclinical period

Male students at ages under 21 numbering 806, included 11 9% of negative Mantoux reactors compared with 5 0% among male controls of similar ages, male students of age 21 and over, numbering 300, included 9 3% of negative reactors compared with 3 2% among male controls of corresponding age In each case the excess of negative reactors was 4 times the standard error and therefore significant The proportion of reactors to 1 10 000 tuberculin were much below, and the proportion of reactors to 1 1000 were above the corresponding proportions in the male control group at both ages The proportion of weak reactors (positive to 1 100 tuberculin) was above the control figure at ages under 21

The comparison establishes the fact that preclinical male medical students are less often and less strongly tuberculin positive than London controls of similar age This was also true of female medical students with respect to the strength of positive reaction and probably also with respect to the frequency of any kind of positive reaction

No case of pulmonary tuberculosis requiring treatment was found at the first examination The incidence of radiological lesions in males was otherwise similar to that in the control group at the same ages Calcified "primary" lesions occurred in 1 7% and 6 1% respectively of students under and over age 21

Re examination after one year of 192 students initially positive to tuberculin showed an increase in sensitivity in 29% and a decrease in 13%, including 2% whose reactions became negative Of 61 initially negative to tuberculin only 33 remained negative after a year, and of 38 retested after two years 15 remained negative The proportion registering an increase in sensitivity was significantly greater than amongst male controls coming from towns (14%) but was the same as that found amongst voluntary hospital nurses

Boys in Naval Training

Two Royal Naval training establishments were included in the survey The first gave a period of about one year's general training to a comparatively large number of boys, the second a period of about four years training in engineering subjects to a relatively small number of boys selected by competitive examination 796 boys aged 15–16 entering the first and 122 entering the second establishment were examined Of the former group 32% came from the country or from small towns of less than 8000 population

In the first establishment the proportion of Mantoux negative reactors was 34% Of those coming from the country or from small towns 40% were Mantoux negative, of those from larger towns 31% were Mantoux negative Boys entering the second establishment showed 21 3% of negative reactors A group of 66 London boy controls of similar age showed 12% of negative reactors

The frequency of radiological lesions was not significantly different from that in the small London control group No tendency for tuberculin *sensitivity* to increase in any way comparable with that found in the hospital groups was found on re-examination after one year

In relation to the rest of the survey, this group of boys is chiefly of interest in so far as it gives an idea of the apparently much lower level of tuberculin sensitivity (and presumably of tuberculous infection) existing in rural districts as compared with London

* * *

The routine work of the survey was stopped during the period of disorganisation immediately after the outbreak of war and was resumed in March, 1940, with certain unavoidable modifications Work on the volunteer control group has become almost impossible since many volunteers have been transferred to districts remote from London while many others have joined the Services Alterations in the working hours of tuberculosis dispensaries have seriously interfered with the examination of contacts Changes in the distribution of medical students have increased the difficulties of routine work in this group, although examinations are being continued so far as possible

Reorganisation of the London hospitals has abolished the clear distinction between nurses in voluntary hospitals and those in municipal hospitals The value of the survey in this group has, however, become more widely recognised and opportunities for expansion have been offered far in advance of those available before the war A large increase has already taken place in the number of nurses under observation and results obtained so far suggest that the survey may eventually add substantially to our knowledge of the epidemiology of tuberculosis among nurses

Wherever full re-examination is impossible the attempt to maintain contact with volunteers through a postal follow-up is being continued

RADIOLOGICAL CHANGES DURING OBSERVATION

One of the most important parts of the survey is the assessment of the rate at which pulmonary tuberculosis develops in the different groups of persons originally free from the disease, and of the factors which lead to the development of lesions Between 1931 and 1939 many such cases were observed especially in the contact group These radiological changes were analysed in some detail in the original report, and figures were prepared showing the rate of development of pulmonary lesions per thousand person-years of observation in the various groups in the period Sept 1931 to Aug 1939 During the first year of the war many more cases of phthisis were recorded and it became clear that more reliable conclusions would be reached by extending the period of observation There was moreover an increasing suggestion of a useful correlation between the tuberculin reactions and the rate of development of tuberculous lesions For this reason it was considered wise to defer publication of figures on these points until the position became clearer, and it is hoped to publish a further report later One point is clear In the contact group, after those suffering from pulmonary tuberculosis on first examination have been excluded, the remainder, originally free from disease develop pulmonary tuberculosis at a steady rate which seems to lie between two and three per cent per annum The value of repeated annual review by X ray of contacts over age 15 and originally X-ray negative is thus very great, especially as the cases so discovered usually carry an excellent prognosis

The organisation and field work of this survey could not be carried on without the help of many persons whom it is impossible to single out for individual thanks I wish, however, to express my gratitude to the Prophit Tuberculosis Survey Committee of the Royal College of Physicians for their wise guidance and for permission to publish this summary

---

SCOTLAND

HOSPITAL CONTRIBUTORY SCHEMES

THE British Hospitals Association with sassenach modesty disclaims any wish to interfere with purely Scottish affairs, but it has gently reminded the Scots that it might be unwise to assume that what concerns Scotland cannot in any circumstances concern the rest of Britain, and that cooperation between the Scottish and English bodies interested in the future of voluntary hospitals is important At the annual meeting in Glasgow of the Scottish branch of the association the representatives agreed that they must stop swithering and make up their minds about contributory schemes, and Mr J D Wyllie of Kilmarnock moved a resolution in favour of their institution and suggested consultation between the different interests involved with a view to setting up reciprocal and as far as possible, uniform schemes Scotland's experience of them has so far been limited but successful and Mr Wyllie pointed out that an extension of national health insurance to include hospital treatment as a statutory benefit would mean their death He thought also that the independence of the hospitals would be affected if the money came from the state, while contributory schemes did not affect hospital self-government nor risk losing voluntary donations Dr David McKail of Glasgow protested that the people of Scotland were unfamiliar with the details of these schemes and he objected to being rushed He did not see how they could escape from a whole-time service with adequately paid medical officers The resolution was, however, approved by a large majority

PROFITING BY EXPERIENCE

Our two chief protections against ship-borne smallpox are vaccination and the surveillance of passengers and crew where a case has occurred War conditions have increased the risk and have made the surveillance of suspects more difficult, and Sir Alexander Macgregor in his report of the recent Glasgow epidemic thinks that the lesson we should learn from it is the adoption of immigrant vaccination as a routine precaution The story of the Glasgow epidemic, he points out, would probably have been different if all susceptible members of the crew and passengers had been quietly vaccinated when the ship left Bombay—a port which was known to be infected Sir Alexander draws a striking parallel with the epidemic of 1929 when the ss *Tuscania* landed a confluent case of smallpox at Marseilles and 13 of the crew and a considerable number of the passengers contracted the disease in this country After this hint the shipping companies trading with the East wisely took the precaution of paying stricter attention to the vaccination of their crews with such good results that it was possible to close the Glasgow smallpox hospital with the exception of two wards reserved for emergencies Today it is imperative that we should do everything to prevent the access of infection to this country and Sir Alexander accordingly urges that vaccination should be made a condition of travel for all passengers sailing to this country from eastern ports who have not been recently protected He is confident that members of the Merchant Navy would be willing to be vaccinated from time to time if the reason for the precaution was explained to them

RUSSIAN CONFERENCE

THE Institute of Experimental Medicine of the USSR met recently to discuss some of the practical and immediate scientific problems which have for the time superseded more theoretical studies A report of their discussion, cabled to this country by Professor GRASHCHENKOV of the Moscow Neurological Clinic, is full of stimulating information but is tantalising too, because it was naturally impossible in a cable to go into detail about the many promising lines of research now being pursued by Russian scientists He reports that in the past six months the clinic, working in collaboration with a mobile field hospital specially staffed and equipped for neurological work, had treated 600 compound wounds of the head Workers there have been much impressed with the value of sulphonamides, and have used sulphanilamide, sulphapyridine and sulphathiazole in proportions varying with the organisms found on wound culture Professor LURIA, at a branch clinic of the institute, is studying the treatment of aphasia and other focal brain lesions Professor KUPALOV, a pupil of Pavlov, finds that injury at the highest brain level interferes with the synthetic action of large areas of cortex, producing torpor and neurotic symptoms Another pupil of Pavlov, Professor ROSENTHAL reported his studies on the elaboration of temporary conditioned reflexes in those with brain injuries, he assesses the initial degree of disturbance of cortical processes, and then tries to estimate—from the speed with which the patient acquires a conditioned reflex—what degree of recovery of function may be expected Other members of Pavlov's laboratory have found that long periods of drug-induced sleep are particularly useful for cases of cerebral contusion

NERVE REGENERATION

Regeneration of peripheral nerves has been studied by Professor LAVRENTJEV, he has used fixed pieces of nerve and spinal cord as transplants for bridging gaps in nerves, and finds he gets his best results with formalinised nerve because it acquires blood-vessels quickly and also delays the proliferation of connective tissue and fibrous elements in the scar Heat was the only thing which seemed to hasten nerve regeneration He suggests ligating the vessels of a nerve as a method of preventing the outgrowth of nerve-fibres and the formation of neuromas Professor MAGNITSKY presented a study of the chronaxie of peripheral nerve after full and partial disturbance of its functions Professor OREKHOVICH has studied the metabolism of degenerating and regenerating nerves and finds special histolytic enzymes at work during regeneration

TYPHUS

Work on the specific prevention and early diagnosis of typhus of the classical louse-borne type has been carried out at the laboratory of Professor SMORODINTSEV Discussing this, Dr LEVKOVICH said that for the first time it had been possible to carry out, in an epidemic area, a large scale investigation of a vaccine prepared at the All-Union Institute of Experimental Medicine according to a modification of the Weigl technique The original Weigl vaccine, it will be recalled, was prepared from the intestines of infected lice Cox vaccine was also tested under epidemic conditions, this has been supplied by the representatives of the American Red Cross and was prepared from growths of *Rickettsia prowazeki* in the yolk sacs of developing fowl embryos and treated with phenol and formalin In animal experiments these vaccines were compared with the Durand-Sparrow vaccine made from the lungs of infected laboratory animals The Cox vaccine was shown to be the most effective of the three and the simplest to prepare In the same laboratory the early diagnosis of typhus was studied by means of a complement-fixation test carried out at low temperature The reaction is said to be sensitive and strictly specific, giving positive results as early as the first or second day of illness—a highly important finding It will be recalled that I A Bengtson[1] in America has obtained positive results in endemic flea-borne typhus with a complement-fixation test in which she used as an antigen a suspension of rickettsias, the reaction was positive six or seven days after the onset and followed a course similar to that of the Weil-Felix reaction A somewhat similar result was obtained in Q fever[2] but these reactions were carried out at 37° C The earlier positive results in the Russian work are presumably due to the low temperature These findings recall the work of R L Kahn,[3] who has found that the reaction bearing his name is intensified if carried out at 1° C, but he considers that such strong reactions at low temperatures are of "general biological" rather than syphilitic type A fuller account of the Russian work should be keenly interesting

INSECTICIDES

Professor PETRISHCHEVA has devised ways to make insecticides from waste and cheap half-processed chemical by-products and from wild plants Nearly 150 types of plant with insecticidal powers have been found in one of the Siberian regions, and several of the substances isolated have been tested against lice, they have proved effective for the disinfestation of clothing and vehicles, including railway carriages Rossisky[4] has published an account of the use of 'Nassecamoyad,' a 10% solution of kerosene-carbolic soap, and also of 'Solvent,' a product retaining the highest homologues of benzol and toluol prepared by fractional distillation He finds that nassecamoyad kills lice quickly without irritating the skin, and its protective action lasts 2–4 days The fumes of solvent destroy lice in 9–12 minutes, this substance too is harmless to human skin Heat treatment of clothing, though doubtless used, has not been mentioned lately by Russian workers, their attention having been directed towards the preparation of efficient insecticides Chasovnikov[5] has written of the use of solvent in the field

BACTERICIDAL STUDIES

Professor YERMOLEVA discussed the use of lytic agents in intestinal disease Good results are reported from the use of small amounts of 'Sulphadine' during phage treatment Bacteriophage has, of course, been used in bacillary dysentery for many years, notably by A Compton[6] in Alexandria Sulphadine treatment has been described by Bobrovolskaia,[7] who gave it first to children suffering from dysentery complicated by pneumonia. It benefited both conditions and this led him to use it in uncomplicated cases of dysentery with excellent results The dosage used was small, not more than 0 7 g a day, with an average total dose of 1 1 g In other countries sulphapyridine, sulphathiazole and especially sulphaguanidine have been used with success in bacillary dysentery but in larger doses than those quoted for sulphadine Professor TOKIN as a result of ten years research has been able to establish that many plants have bactericidal properties, especially ordinary onion, garlic, radish and probably citrus plants Exposure for 5, and in some cases 3, minutes to the vapour of these plants is said to inhibit and sometimes kill such organisms as streptococci, staphylococci and intestinal bacteria

In England Now

A Running Commentary by Peripatetic Correspondents

ON April 4 I set out westwards from Kweiyang in West China with seven companions, one a doctor, and one our unqualified anæsthetist We had a supply lorry and our two special vehicles—the mobile operating-theatre and the mobile X-ray department On our journey over the Burma Road we visited several hospitals and were able to do some X-ray examinations for which missionaries had long been waiting At Hsiakwan we were held up by trouble with our supply lorry, and I had several glorious days on Hsiakwan mountain, where I made one ascent almost to the snow, reaching 11,000 ft The many kinds of rhododendron were wonderful

When we came to the Yunnan-Burma frontier at Wanting on April 22, there was an air-raid alarm in progress, and we crossed into Burma without having to stop or show papers to anyone The frontier was not well marked, and even though in Burma, we seemed for practical purposes to be still in China In Lashio we heard that a Japanese drive northwards from the South Shan states was seriously threatening the town and the road from Lashio to Mandalay We still had time to get through, but we realised that the road would almost certainly be cut behind us This would probably mean that our expensive vehicles would have to be abandoned, even though we might be able to get away on foot We were at this time taking our instructions from American Army HQ We asked the senior American Army officers in Lashio whether we should go on or not They said we had a chance of doing a good job of work if we did So being keener ourselves on going forward rather than back, we decided to take only one supply lorry and to send our valuable equipment back towards China We set out in the early hours of Sunday morning and drove down to Maymyo Shortly after this the Japanese reached the road and spread along it, taking Lashio and then spreading rapidly northwards so that they reached Myitkyina, in the north of Burma, in an incredibly short time

Maymyo, normally a fashionable hill resort much frequented by society, we found deserted We were given tea at a house, and were invited to take away anything we liked If we had had the means to carry them we could have brought away a marvellous collection of strange things The civil hospital was in the process of packing up, and here again we could help ourselves to anything we liked if we felt so disposed From Maymyo we went on the same day through the ruins of Mandalay without stopping, and then across the great Ava bridge, blown up a few days later, which took us to Sagaing, on the west side of the Irrawaddy. Here we found accommodation for ourselves in the hospital The town was pretty well deserted, and there was no buying or selling Soon after we left Sagaing next morning we saw it being bombed and partly set on fire

We moved that day to near Shwebo, and so fell in with Major Seagrave and his surgical unit He is an American missionary doctor, now acting as a surgeon in the U S army We stayed in the same Burmese house with his unit After about three days there we were told to add ourselves to what was called a staging section in the British Army This is a medical unit which gives minor treatment to wounded and sick soldiers in transit We reported to No 2 staging section, which was a small unit sitting about in a field where shade was hard to find Shortly after arrival we heard a formation of Japanese bombers coming over, and then began the unpleasant noise of bombs falling rapidly We mostly lay on the ground under the lorry, and soon it was over and we realised that we were all there and unharmed But some men about 150 yards away had not been so lucky, and about 25 casualties were brought to us Then followed a period of intense "blood, tears, toil and sweat," and that night ambulances took our patients away I am afraid some of them had a bad time in transit, and some died who should have lived That evening, having had news of enemy movements, we went on late into the night following a narrow road through dense jungle

Sometimes the road surface was very bad and there were hair-pin bends so acute that the lorry had to go alternately backwards and forwards in the descent The jungle looked glorious to wander in, but we had to keep moving, and there was no opportunity for catching butterflies or picking flowers Next day the road conditions became almost impossible We had to cross dozens of wide dry waterways—or rather there were waterways which were so serpentine in their course that our route crossed the same one repeatedly These were dry and sandy, and over and over again the lorry sank Sometimes we had to cut down branches from trees and stack them in front of the wheels to let them get a grip on the loose sand Vehicles were abandoned at these crossings, and several times we thought our motoring must end Twice we gave our lorry up as lost and began to unpack the more valuable part of our equipment, but thanks to the Army we got through at last, and after doing a lot of hard work on the way our old lorry has now safely reached Calcutta, where it is undergoing a well-earned rest and overhaul This lorry incidentally had an interesting history Originally it was "rescued" by the Friends Ambulance Unit in Rangoon dockyard just before the Japanese arrived Its bodywork was never completed, but in spite of this it was used on battlefields south of Mandalay, later going up to the Chinese frontier, and after this making the long and difficult journey across Burma, Manipur, Assam and Bengal to Calcutta

Next day we reached Shwegu, on the east side of the Chindwin river Here I had the good fortune to see a pair of "paradise flycatchers," really lovely little birds, black and white, with an enormously long tail several times the length of the body The Chindwin was lovely as we travelled up-stream on its broad waters, between hilly, jungle-covered banks and it was easy to ignore the countless rumours, which mostly turned out to be fallacious anyway

At Kalewa, the civil hospital and all its equipment was handed over to me Here we had a lot of casualties to deal with We soon moved out from the hospital, which was too near the town to be safe, and opened up the local monastery as a hospital Here we did some operating Later the RAMC took this place over and we moved on

We borrowed an old Ford lorry, and kept this and our Chevrolet working hard carrying wounded and civilian evacuees towards India and peace All this time everything was tense and unnatural There were no shops, no normal living conditions The only people we saw were army units and the tragic hordes of Indian evacuees The Indians were imported into Burma by the British because the Burmans could not be made to work With the exit of the British the Indians came too, because apart from British control they could not live in harmony with the Burmese They were a pathetic sight, and when the lorry was so packed that it was impossible to wedge in anyone else it was difficult to deal with the old men and women and mothers with babies who knelt on the ground to implore for help on their long and weary march In one camp where we spent a few days a baby was born, its mother went on next morning Here, also, we received a two-day-old baby which had been found lying by its mother's corpse at the deserted civilian hospital We gave it to a native VAD who was doing splendid work looking after British and Indian wounded. Here at Tamu I met three men I had known at Thomas's, and one who had been at St Paul's School, and just missed D A Patterson, an old schoolfellow. He is a padre, and was at Shwebo just before we went there.

---

[6] *Brit med J* 1942 i, 719
[7] *Soviet Vrachebny J* April, 1941, p 277

After Tamu we followed a mountainous road over the Chin hills, and so came to Imphal, the capital of Manipur state. Here there had been one air-raid, and the civil population had left the town and not returned. There was not even anyone to remove the corpses decomposing in the streets—incidentally we did a fair amount of undertaker's work in Burma. At Dimapur we were entertained and well fed at the rest camp. The Army then gave us, including the lorry, free passes, so a few days later all our equipment, not to mention our personnel, completed the trip and landed in Calcutta.

H T L

* * *

It cannot often fall to the lot of a reviewer to discuss the first edition of a book and then, after an interval of a quarter of a century, to be asked to review the second edition. And when the work happens to be D'Arcy Thompson's *On Growth and Form*[1]—as I sincerely believe, the greatest contribution to biological science made in our generation—the privilege is of an altogether unusual kind. The first edition wandered with me everywhere; the binding was nibbled by silver fish in Australia and by cockroaches in Hawaii. The passage of twenty-five years has in no whit diminished the pure intellectual joy imparted by its reading. No brief account of the work can make real the beauty of the language, the profundity of the scholarship, or the perfectly rounded and patinated maturity of the whole thing. His father's *Daydreams of a Schoolmaster*, a real classical scholarship, a lifelong study of biology and an aptitude for mathematics are some of the factors that go to its making, but to all this there must be added that serenity of judicial outlook that refuses to be attracted by the new merely by reason of its novelty. As I re-read the old matter in the book and delighted in the new, I felt that its reading should be made compulsory for every one of the younger men who are today suffering, as perhaps never before, from a lack of historical background in the biological sciences. By them it should be read as a monumental example of the fact that the best scientific work can still be best presented without any distortion of the beauties of the English language. It should be read as an outstanding lesson in the exercise of mature and intellectual honesty of judgment and of restraint in dealing with certain fashionable doctrines. Indeed, there are occasions in which restraint has gone almost too far. There is much that is tantalising in the statement "and I leave this great subject on one side not because I doubt for a moment the facts nor dispute the hypotheses nor decry the importance of one or the other but because we are so much in the dark." One is left with the feeling that if that darkness is to be illuminated the author is likely to have a suggestion as to whence the light will come. Again, with shrinkage forms, enough has been told to make us realise the vast importance of the subject. The author says "The subject is new and hardly ripe for full discussion but it holds our promise." That is easy to realise. Will the promise be fulfilled? Shall we ever have the full discussion? The two editions of this book have been written during two wars. The scholarship that has gone to its making transcends all war and the reading of the whole thing makes war more remote—yet far more beastly in contemplation. We cannot await another war to usher in the dawn of a third edition in which some of our curiosity on shrinkage and many other things may be satisfied. Meanwhile we can only rejoice that there is still among us the master who can lead us through that strange world in which physical forces and chemical reactions play their parts as determinants of living form, and, by reason of the beauty of his diction, do it so that no part of the journey is dull or difficult to follow.

* * *

In 1928 a lady had a gastric ulcer. While she was in hospital, her physician looked at a laboratory report and said to the nurse, "There's occult blood too." The lady decided that they both looked very grave, and when she asked the nurse what it was all about the nurse refused to tell her. A year later she pursued her investigations further, when again under treatment. This time some one told her that occult blood meant that there was a minute amount of bleeding from somewhere in her inside; she repeated this explanation to two nurses, who dissolved, for some reason best known to themselves, into fits of laughter. Her ulcer was healed, but the worry remained. The other day, reading one of the *Daily Mirror* articles about venereal disease, the explanation flashed into her worried mind. She had VD. There is a moral here somewhere and it is obscurely connected with the moral of your story in "Three-in-One Doctor" (Oct 3, p 402), but both take a bit of drawing.

Letters to the Editor

THE CHRISTMAS GIFT

SIR,—It is always with a feeling of hesitation, perhaps of fear, that I address this letter to you at this time of the year; hesitation and fear lest I should fail to state the cause effectively to your readers. But in my 25th year of office as president of the Royal Medical Benevolent Fund and as an old man myself, may I once more appeal on behalf of old doctors and their loved ones that the Christmas Gifts fund be continued in 1942. A gift of £2 to each of our beneficiaries on Christmas Day to bring some comfort, perhaps warmth or an unaccustomed enjoyment to homes where every penny has to be considered, is my desire. Will all friends who have helped me in the past do what they can again this year, and will others come forward as contributors to take the place of those who have had to drop out.

All contributions should be addressed to the hon. treasurer, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, London, S.W.15, and cheques should be made payable to the "Christmas Gifts Fund."

THOS BARLOW,
President, RMBF.

CERTIFICATION OF DEATH IN INFANCY

SIR,—Dr Miller's article is of great interest to those who are not satisfied with our infant mortality rates. It was shown by the Registrar-General in his 1934 and 1937 reviews that the rates of England and Wales compared unfavourably with the national rates in Norway, Sweden or Holland. It has long been realised that certification of the causes of death of young infants leaves much to be desired, and the Newcastle Health Department is rendering useful service in persistently calling attention to it. Much light has been thrown, however, both upon the causes of neo-natal deaths and upon the possibilities of reducing them by the Chicago work, and conditions in that city are not very different from those in our own towns. In view of this work and the Ministry of Health's investigation in Holland before the war, we are not entirely ignorant about the reasons for the retarded improvement in our own country. But it is useless to press for reforms unless we are sure that they are likely to help towards the desired result, and some of Dr Miller's suggestions seem to require examination on that and other grounds. He recommends that a mechanism might be provided which would enable a doctor, in cases which do not require notification to the coroner, to indicate that he does not know the cause of death, so that he can obtain an autopsy before giving a final certificate. There is some confusion here, for, if the doctor does not know the cause, the death is one which *should* be notified to the coroner, the registrar being instructed to notify any death "the cause of which appears to be unknown." A mechanism to enable the doctor to obtain an autopsy in such cases is already in existence. If the doctor informs the registrar that he is uncertain about the morbid condition which caused death, the coroner will be notified and can order an autopsy without inquest if he is satisfied that death was from natural causes. There is no other means of enforcing an autopsy, and Dr Miller has made out no case for alteration of the law in this respect. In 15% of the infant deaths studied the investigators at Newcastle could not discover a cause, but we are left to surmise that, instead of using the mechanism outlined above, the certifiers had preferred in most instances to write down on the certificate what they considered to be the most likely cause. In another fraction of about the same size the investigators differed from the certifier as to the cause, and considered that injury at birth was often certified otherwise. They also concluded that prematurity and gastro-enteritis were over-certified. There seems to be a common idea that to write injury at birth on a death certificate will mean an inquest, but 1933 statistics showed that inquests had been held on only 6·3% of deaths classed to that cause, whilst in 3% the coroner had ordered an autopsy without inquest, in 1·1% no certificate had been given and in the remaining 89% the coroner had accepted the certificate. The chance that such an entry will lead to an inquest is, therefore, a small one.

---

[1] Cambridge University Press. Pp 116. 50s.

The way to ensure reliable national statistics of infant deaths is to use the machinery in existence in order to obtain an autopsy in every case of serious doubt. This is a difficult path to follow, but certifiers must decide whether the other considerations which press upon them in such cases are to be allowed to retard progress towards knowledge and towards the discovery of means of preventing such deaths in the future. The most recent figures available (Registrar-General's Review for 1933, pp. 145–157) show that in London the percentages of infant deaths certified after autopsy without inquest were much greater than in the rest of the country. Dr. Miller also recommends revision of the International List of causes of infant deaths by a committee of clinical pediatricians. The list was carefully revised in 1938 by committees including such specialists both in this country and in America, and it will normally be revised again in 1948. Although your editorial states that "Miller shows good cause indeed for a revision of classification," I do not think that he himself will claim that he has advanced cogent arguments for an immediate revision. The main fault found is that inquiries are not sent by the Registrar-General asking for more information when certain causes, notably prematurity, are certified. But if an infant aged 1 or 2 months is stated to have died of prematurity alone the inquiry would have to be whether there was any other cause not mentioned on the certificate which the certifier considered to be *more important* in causing death than prematurity. If an associated morbid condition was not considered more important, the classification of the death would not be affected by mentioning it; consequently the certifier would in fact be asked whether he had omitted what he considered to be the most important cause and entered only a subsidiary one. Apart from the natural annoyance engendered by such a question, would accuracy be appreciably advanced thereby? To inquire more often of the certifier about infant deaths where there was no autopsy would be unlikely, in my opinion, to add much to our knowledge at present.

Dr. Miller's first two recommendations deal with methods of informing the medical profession more fully on the importance of accurate death certification, and on this general question I would point out that the book of medical certificates does contain notes and suggestions which supply a good deal of the desired information. He recommends that a special form of death certificate for infants, including information about birth-weight, feeding and position of child in family should be introduced. Birth-weight and feeding cannot be usefully studied apart from many other factors, such as heredity, social position, mother's health and occupation and so forth, and the registrar would not be in a position to ask the questions necessary. These matters would surely be much better investigated *ad hoc* in a few areas than by attempting to amass national statistics, even if the administrative difficulties could be overcome.

Southport. PERCY STOCKS.

ANÆMIA IN PREGNANCY

SIR,—Your leader of Sept. 19 seems to take at their face value the figures given by Hamilton and Wright in their paper on the value of the administration of iron to pregnant women. Their two groups treated with iron and untreated each numbered 196 and had initial hæmoglobin levels of 75% and 79% respectively. If these two groups of pregnant women were samples of the same population, this difference in the average hæmoglobin level of the two groups must mean that the standard deviation of the population is at least 18. Such a standard deviation means that the final hæmoglobin levels of the two groups, 77% for the treated and 70% for the untreated, is likely to occur by chance, so that it is improper to conclude that iron had any effect on the hæmoglobin level at all. It is of course improbable that the standard deviation of the initial hæmoglobin of 100 pregnant women is as much as 18. The difference between the average initial hæmoglobin of the two groups may very well be due to the unfortunate planning of the investigation. The untreated group was seen on one day of the week, the treated on another, so that whoever estimated the hæmoglobin was bound to be biased unconsciously by knowing to which group any individual estimation belonged. This regrettable fact and the statistical argument given above make Hamilton and Wright's figures an uncertain basis from which to draw any conclusions about the value of iron administration to pregnant women. This argument, of course, does not prove that iron administration is valueless, but it would be a pity to force every pregnant woman to take an indigestible and tooth-blackening medicine for several months all to no purpose, and to use these figures to recommend the fortification of bread with iron.

What is striking, however, is that iron treatment had such a *small* effect on women with such comparatively low hæmoglobin values. Fullerton found some years ago that iron treatment brought the hæmoglobin level of pregnant women at term to a figure about 13% above the untreated figure of 75% (estimated by the same method as Hamilton and Wright and with apparatus apparently calibrated to the same 100%) in spite of the poorer economic status of his patients. This suggests that it was not really a low iron intake which determined the low hæmoglobin of the war-time patients but a war-time deficiency of some factor concerned in iron utilisation. Evidence has recently been presented that vitamin C conditions the utilisation of liver in pernicious anæmia (*Lancet*, 1942, ii, 278), and it is well known that iron treatment is useless in the iron-deficiency anæmia of scurvy unless vitamin C is given as well. It is a general experience in this country that plasma vitamin C levels are now much less than they were in peace time. Would Hamilton and Wright consider it worth while to continue their observations by estimating the value of supplementary vitamin C in raising the hæmoglobin of pregnant women?

Oxford. R. H. MOLL.

TUBERCLE FOR TUBERCULOSIS

SIR,—It is with considerable misgiving that I have been noting the use in your annotations and leading articles of the word tubercle when tuberculosis is meant. And I see that the *Times*, following in your footsteps, published a leader last week entitled Treatment of Tubercle. Tubercle in the place of tuberculosis has been used colloquially by some tuberculosis workers for a long time, but on the whole its use has been frowned upon, and one certainly seems to hear it less and less. Is there any justification for its use in print apart from this? The lay public, I feel sure, knows tuberculosis much better than tubercle, and probably also spells it more correctly in spite of its greater length. And in foreign languages we certainly find no corresponding use of another word in place of (Fr.) *tuberculose*, (Ger.) *Tuberkulose*, &c. THE LANCET has been looked up to for many years as a champion of jargon eliminators. Hence its failure—if such it is—in respect of "tubercle" is all the more noticeable.

Staines, Msx. G. GREGORY KAYNE.

*** My predecessor James Wakley, who was something of a purist, wrote on the announcement of Koch's discovery—"But the organism of tubercle has hitherto eluded research" (*Lancet*, 1882, i, 655). And later in that same year Prof. Wm. Pirrie of Aberdeen entitled an address "the Infectiveness of Tubercle" (*Ibid*, 1882, ii, 171).—ED. L.

HERNIOPLASTY

SIR,—Squadron-Leader Arthur in his interesting article on the treatment of inguinal hernia in the R.A.F. does not discuss the recurrence rate following the modification of McArthur's hernioplasty he describes. My former chief, Prof. P. P. Debono, has been using an almost identical modification at the Central Civil Hospital, Malta, for over fourteen years and the number of cases he has done must amount to several hundred. As far as I am aware neither the technique nor the end-results have ever been published, and up to the beginning of the war the statistics had not been collected. However, I believe I am correct in saying that it is Professor Debono's impression that the recurrence rate is very low indeed He does not use fascial grafts as a routine but only in selected cases and he has devised a useful fascia carrier faintly resembling a Reverdin suture carrier For some time I have been using the same technique with the difference that I use silk or cotton instead of catgut So far the results have been gratifying

London, E 1 A J CRAIG

Obituary

JOHN WALTER CARR

C B E, M D LOND, F R C P & S

Walter Carr, who died on Sept 29, at the age of 80, belonged to a generation of physicians, now almost extinct, who took an interest in all departments of pure medicine He was fellow of both the senior colleges and had gained experience of diseases of children at the Victoria Hospital, of diseases of the chest at the Brompton under Douglas Powell and of diseases of the nervous system at UCH under Charlton Bastian

Vandyk

Only child of John Carr, JP, a chemist who had passed on his ambition to be a doctor to his son, John Walter was born in London and educated at University College School and Hospital where he qualified in 1884 He took his London degree in the following year with first-class honours in medicine, surgery and midwifery His first honorary appointment was as assistant physician to the Victoria Hospital in 1889 and he remained on the staff till he became consulting physician in 1920 Outside medicine one of his chief interests was education, and when he was appointed assistant physician to the Royal Free in 1893, and a few years later lecturer in medicine at the women's school, he worked wholeheartedly for students His teaching was largely modelled on that of his old chief, Christopher Heath, a former PRCS He was also on the council of Epsom College and was associated with the examinations for the state registration of nurses He was a freeman of the City of London and from 1914 a member of the court of the Haberdashers Company which he also served for a term as master In such duties, especially those connected with the Drapers and Haberdashers schools, he found solace as professional claims diminished He was a great traveller, but in recent years a severe multiple arthritis deprived him of the long walks which he had enjoyed both at home and in Switzerland

About 40 years ago Carr was smitten with writer's cramp, and though he learned to write with his left hand this disability and his heavy hospital and teaching duties prevented him from contributing as much to medical literature as he might have done Perhaps his most important paper was on non-tuberculous posterior basic meningitis in infants, the first complete account of the disease published in this country, in which he pointed out its probable relationship—later to be confirmed by Still—to cerebrospinal fever His official addresses to the Medical Society of London were common sense, expressed with dry humour spiced with cynicism Their matter after twenty years is still the controversy of the hour In "Medical Ambitions and Ideals" he sets out the dangers he saw inherent in a state medical service in which the ministry of health took the place of the medieval church with its chief medical officer as an uncrowned pope In "A Medical Utopia" he pictures the tonsil-less, appendix-less, vaccine-filled being which this benevolent autocracy might be expected to produce For himelf he would rather see England free than healthy, and he urged his colleagues not to lose sight of primary causes when seeking to ameliorate secondary consequences

His CBE was in recognition of his work at the hospital for officers, carried on in a part of the Royal Free during the last war His knowledge of affairs made him a valuable member of committees, and his straightforward fearless but tempered judgment carried great weight both in the councils of his hospital and of the RCP where he served as censor 1926–28 He married in 1895, Jessie, daughter of Walter Griffith, of Streatham Hill She died in 1937 and they leave a son and three daughters, two of whom married medical men

GEORGE ARTHUR EWART

B A CAMB, F R C S

Mr G A Ewart, surgeon to St George's Hospital, died on Oct 2, at the age of 56, after one day's illness He was the son of Cossar Ewart, FRS, professor of zoology in the University of Edinburgh, and was educated at Clifton College, Edinburgh University and Christ College, Cambridge At both universities he gained scholarships, and at Cambridge he took a first-class in the natural sciences tripos, besides representing the university at cross country running Qualifying at St George's in 1912, he took the FRCS two years later, and was shortly afterwards appointed to the assistant staff, which he was to serve for fifteen years before proceeding to the senior staff During last war as a temporary major RAMC he worked in France, and in the 4th London General Hospital at home His other peace-time appointment was to the Hospital of SS John and Elizabeth to which he was consulting surgeon at the time of his death

As Ewart grew older his surgical interests became more and more concentrated on the surgery of the abdomen, and, in particular, on acute abdominal diseases He had a flair for this work, and combined sureness of diagnosis with a technique which was equally sure, but which he loved to make dramatic His long service as assistant surgeon had given him an exceptional experience in abdominal emergencies, and even when on the senior staff he was always keen to do this kind of work himself As a teacher Ewart was effective—one of those men who belittle their own knowledge to give their students the feeling that the gulf between themselves and their teacher is not unbridgeable, and that their difficulties are really understood

Many generations of George's students will remember with gratitude the friendly hospitality which they received from Ewart and his family, and many others who were of his profession or who shared his abounding interest in country things—shooting, natural history and photography He married in 1914 Dorothy, daughter of Sir George Turner, surgeon, rear-admiral and writer, and they had one son and two daughters

EDWARD FAWCETT

M D EDIN, F R S

ON Sept 21 Professor Fawcett, who for forty one years held the chair of anatomy in the University College and University of Bristol, died suddenly while walking in the street He had occupied a pre eminent place in the work of the university and in the affections of many generations of medical students

Elliott & Fry

He came to Bristol as a young man in 1893, four years after he had qualified at Edinburgh University, to be the first full-time professor of anatomy in University College, and he captured the attention of a none too orderly crowd of medical students immediately by his capacity to lecture, to demonstrate, to illustrate by drawings and by his power of keeping order Perhaps he had other gifts besides his grasp of anatomy that gave him authority in his class-room He was an all-round athlete, and as a cricketer might have found a place in almost any county team Edward Fawcett was born in 1867, the son of Thomas Fawcett, BA, at Blencow, near Penrith, and was educated at the grammar school there and at Edinburgh University By 1887 he had become a demonstrator of anatomy in the Edinburgh School of Medicine and after he graduated in 1889 he was demonstrator of anatomy at Yorkshire College Leeds till he was called to Bristol In 1906 he became dean of the faculty of medicine and he played an important part in organising the faculty when the university was given its charter three years later Successive vice-chancellors relied implicitly upon his judgment and experience in all that related to medical study, and their confidence was justified For he was able and diligent in his attention to affairs Academic honours naturally came to him, and in 1906 he won the gold medal for his MD thesis at Edinburgh In 1909 he was made president of the anatomical section of the International Congress of Medicine at Budapest, and from 1927 to 1929, he also held that office in the Anatomical Society

Fawcett's researches into the development of the human skeleton and of the mammalian chondrocranium won for him the FRS in 1923, but the beautiful wax models which illustrated his work have been lost by enemy action Apart from his prowess at cricket Fawcett had many hobbies He was an indefatigable cyclist and used his bicycle on many expeditions to study church architecture He was a first-rate photographer, and some of his best work illustrated his presidential address to the Bristol and Gloucestershire Archæological Society in 1936 when he spoke on anthropophagous sculpture and royal arms in churches For many years he represented Bristol on the Central Council for the Preservation of Churches, and for the past months he had been rephotographing local churches for the national collection Prehistory was another of his recreations, and he was energetic in his support of the University Spelæological Society of which he was for many years president, and he was the enthusiastic comrade of the youngest undergraduates on expeditions to explore the caves of the Mendips

Professor Fawcett married in 1895 Edith Dora Wordsworth, and he leaves her with a daughter and a son, A W Fawcett, surgeon to the Sheffield Royal Infirmary

FRANK HOLT DIGGLE

OBE, MB MANC, FRCS

Holt Diggle died at his home in Dunham Massey, Cheshire, on Sept 30 He was dressing when a heart attack took him away with tragic but merciful suddenness Only back a few days from a short holiday in the English Lakes he was at work as usual on the day before his death Born in the Lancashire town of Heywood fifty-seven years ago, he took his medical course at the Manchester University, graduating MB with second-class honours in 1909 Although his contemporaries in the medical school were a galaxy the like of which the school may never know again, Diggle's star was not dimmed by comparison In face of keen competition, he took medals in anatomy, gynæcology and medicine, these, in addition to the Bradley surgical scholarship and the Agnew scholarship for diseases of children In 1910 he obtained the English conjoint qualification and three years later the fellowships of the English and Edinburgh colleges of surgeons Before joining the Army in 1915 his experience included appointments in Manchester and London and a spell of general practice in Bradford Till 1919 he served as a surgical specialist in the RAMC, and for his services in the Near East he was awarded the OBE and mentioned in dispatches

J Ingham & Sons

The war over, Diggle held resident and honorary appointments in hospitals in Birmingham, but in 1920 on his appointment as oto-laryngologist to the Ancoats Hospital Manchester, he came home again, and although later he joined the Manchester Ear Hospital, the Christie Hospital and Holt Radium Institute and was consultant to many other hospitals outside the city, it is for his work at Ancoats that he will be remembered He was its first aural surgeon, and starting from nothing he built up a big, well-equipped and well-organised clinic Despite heavy calls on his time and energies he made opportunities to write on many problems in his specialty, following closely in the steps of his teacher—the late Sir William Milligan—and the scope of his writings shows the breadth of his interests the rôle of nasal disease in asthma, the influence of disease of the thyroid gland on disorders of the nose, ear and throat, foreign bodies in the air and food passages, the surgical treatment of lacrymal obstruction, cancer of the larynx He attended regularly the meetings of the Royal Society of Medicine and the Manchester Medical and other societies He knew all the important British clinics and had visited many of the foreign ones as well

Diggle's best card in his strong hand was his laryngeal surgery His long training in general surgical technique stood him in good stead, and in the conflict between surgery and ray-therapy in the treatment of laryngeal malignancy, he preserved a nice balance and a fine judgment There was a good deal of the artist in his make-up, sensitive, self-critical imaginative and creative His sensitiveness led him sometimes to misunderstand his fellows and sometimes to be misunderstood His self-criticism drove him to give of his best to all at all times and to demand an exactingly high standard of those who worked with him, though he never stinted praise or thanks as a just reward for good service His self-criticism, too, made him face surgical failure in the Mackenzie tradition asking why and seeking the answer, in success, he had something of Ambroise Paré's humility From the imaginative side of his nature sprang the restless desire to try new ideas and hazard new methods, in his private life it showed itself in an appreciation of the arts and a love of music

Frank Diggle had no absorbing hobby but many interests He played a round of golf with enthusiasm, though it must be admitted that his back-chat was better than his back-swing Essentially a family man, he was at his most likeable best in his home, where his generous heart and happy Lancashire wit shone in their true setting With his widow and daughter we share his memory and mourn his loss

V L

Dr A T NANKIVELL who died at Abingdon Berks, on Oct 3, had been MOH successively for Hornsey, Poole and Plymouth He collaborated with R T. Hewlett in *The Principles of Preventive Medicine*, and wrote a popular primer on *The Science of Hygiene* For many years he was lecturer in epidemiology at King's College, London

---

Infectious Disease in England and Wales

WEEK ENDED OCT 3

Notifications—The following cases of infectious disease were notified during the week smallpox, 0 scarlet fever, 2123, whooping-cough, 845, diphtheria, 860, paratyphoid 5, typhoid 6 measles (excluding rubella), 3801, pneumonia (primary or influenzal), 508, puerperal pyrexia, 172, cerebrospinal fever, 61, poliomyelitis, 33, polio encephalitis, 6, encephalitis lethargica, 3, dysentery 232, ophthalmia neonatorum, 95. No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Sept 30 was 1566 including scarlet fever 455 diphtheria 193 measles 172 whooping cough 217 enteritis 64, chicken pox 56 erysipelas, 44 mumps, 48, poliomyelitis 11 dysentery 52 cerebrospinal fever, 8, puerperal sepsis 23 enteric fevers 10 german measles, 2 glandular fever 1, other diseases (non infectious) 124 not yet diagnosed 86

Deaths—In 126 great towns there were no deaths from the enteric fevers, 6 (0) from measles 3 (0) from scarlet fever 13 (3) from whooping-cough 20 (0) from diphtheria, 72 (6) from diarrhœa and enteritis under two years, and 12 (1) from influenza The figures in parentheses are those for London itself

Liverpool reported 3 fatal cases of diphtheria There were 8 deaths from diarrhœa at Liverpool, 7 at Birmingham and 6 at Manchester

The number of stillbirths notified during the week was 201 (corresponding to a rate of 31 per thousand total births) including 32 in London

---

MEDICO LEGAL SOCIETY—A meeting of this society will be held at 26, Portland Place, London, W 1, on Thursday, Oct 22, at 4 30 PM, when Lieut-Colonel W W Mansfield, MIMechE, will read a paper on disguise in handwriting

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE House is getting more health-conscious A question by Sir Smedley Crooke asking for a mobile immunisation service van for diphtheria to be sent to other cities in view of its success at Portsmouth led to a round of supplementaries like a first-rate political issue Health indeed has become a first-rate political issue

When he announced the completion of the MRC report on tuberculosis the Minister of Health said he had already taken action on a number of points The question the answer, and the supplementaries occupy more than could get their [illegible] columns of Hansard—more than sometimes is radiography and the acquisitions on an important war issue And they plus arrangements for the tr questions Indeed more members rose expert staff is quick action It is questions in The adoption of mass provision of the extra accommodation ing of 30 sets of apparatus envisaged by the Minister will not be held up running of the necessary nurses Perhaps the most important provision announ be hoped that the by the Minister is the authorisation given to local for treatment authorities to grant financial assistance for the maintenance of the dependants of those undergoing treatment lack of going These grants are to be made as part of the public-health service and it will not involve a means test

As to whether these facilities apply to ex-Service men the Minister was not so explicit as on other points but it is clear that an ex-Service man (or woman) is in the same position as any other member of the public The Army do not accept liability for the tuberculosis of men discharged from the Service, unless it is accepted as attributable, which is rare There seems every reason to hope, therefore, that adequate treatment may now become available The Secretary for Scotland, Dr Tom Johnston was pressed to make a full statement from the Scottish angle but preferred to wait until he had consulted with local authorities

Good as the facilities for diagnosis are, everything turns on the facilities for treatment of early cases and—a matter on which Mr Brown did not touch—on treatment and isolation of advanced cases to prevent the spread of infection A rise in the incidence of tuberculosis occurred in the last war and it occurred in Germany and in Russia as elsewhere The need for tackling the problem today is now so clearly recognised that nothing should be allowed to stand in the way It is hoped that special attention will be given to the ex-Service cases and that the differences in methods of dealing with cases, and of accepting financial responsibility for cases, will not be allowed to stand in the way of a nationally efficient system

MINISTER'S STATEMENT ON TUBERCULOSIS

"We are about to begin a new drive against consumption—a drive of a kind never attempted before in this country"

Mr JAMES GRIFFITHS asked the Minister of Health whether he was in a position to make any further statement on tuberculosis —Mr E BROWN replied I am grateful that the committee which was appointed by the Medical Research Council at my request has completed its report which was published on Oct 8 I have kept in touch with the committee and have already taken action on a number of points which are included in their recommendations. To facilitate early diagnosis we obtained priority for the supply of some 30 sets of equipment for mass radiography We are allocating them to large centres of population where they can be used to the best advantage In consultation with local authorities and with the assistance of an expert committee we have arranged for the training of the necessary expert staff the operation of this equipment Deliveries will be gradual and arrangements for operation in the individual districts and for cooperation between authorities must be worked out in detail, but I expect that an effective start will be made in the New Year The extended arrangements for diagnosis will mean some increase in the need for accommodation Additional beds are being allocated to meet this need and action is being taken to meet the needs for nursing and domestic staff Domestic and nursing work in hospitals, incl regarded as war service for which su age-group may volunteer and to w allocated by the Ministry of Lab Service, and I have been in consult league with a view to special attentio the working of sanatoria is being han the necessary staff Immediate ne trained nurses can only be met by a be the trained nurses available Detaile such a distribution and, in particular, effective use of nurses who are comple members of the Civil Nursing Reserv can be temporarily spared without current efficiency of the hospital to attached, will be worked out by my consultation with representatives of th the nurses

Where facilities for diagnosis an available *it is important that those w temporarily for treatment*, which is in t public health no less than their own, sh so without financial anxiety as to the their dependants Local authorities being authorised to grant financial assi by the public for the maintenance of the dependants treatment under the of the home while the bread incurred by *them in account* This assistance will ments which I am now working out authorities as a part tives will be repaid from Exchequer nal ulosis schem tary of State for Scotland authorises making similar arrangements in Scotland

DIFFICULTIES TO BE MET

Mr J GRIFFITHS Is the Minister satisfied able to secure the necessary number of nurses service outlined, and in regard to the assistance since the payments would come out of the Exch be on a scale determined nationally ?—Mr Br scale will be so determined, but the plan is a maintenance and extra grants for standing cha educational costs and rents and things of that now discussing the details with representatives of tion of Municipal Corporations, the County Co tion and the London County Council. We are the light of the local knowledge of my regional list of the hospitals in which the need for nurses is will include a large proportion of the sanatoria, then ask the various training schools to provide a q nurses coming out of training for allocation to We shall also review the Civil Nursing Reserve an staffs in hospitals for current needs with a view to them and attaining the end we all want Replying questions Mr Brown made it clear that the ma ments were not to be on the basis of a means test be part of the public health service The were in touch with other ministries with a view to incidence of non pulmonary tuberculosis which coul to infected milk. On the question of pasteurisation the House to answers which he had given during the

Captain G S ELLISTON asked whether the mass ra sets would be available for selected counties and boroughs where the medical officer of health had approved scheme ?—Mr BROWN We shall work in tion with the authorities The sets are transportable, are best kept at places where they can be used for a

Mr F J BELLENGER Will these facilities both for and for maintenance of dependants apply to that large of men who will be discharged from the Services as a of this disease ?—Mr BROWN They will apply to all w concerned with common tuberculosis and the work d connexion with the arrangements at local sanatoria are a number of discharged Service men in the sanat

SIR FRANCIS FREMANTLE Will the Minister be in touch the ministries of the fighting Services so that they pr tuberculous men from getting into the Services and ha be invalided out later on ?—Mr BROWN The initiative use of mass radiology was taken by the Services

Replying to further questions Mr Brown said th Ministry of Health had under consideration the quest help and encouragement for the after care

r T JOHNSTON, Secretary of State for Scotland, informed r G BUCHANAN that he would make a statement on the heme as it affected Scotland after he had consulted with the al and health authorities on the subject Mr A MAC REY asked the Minister if he was not aware that all this pense might be more or less abortive owing to the present l housing conditions and urged that something must be ie immediately to deal with that problem No further ly was given

QUESTION TIME

Cod-liver Oil and Fruit Juices for Children

r H BROOKE asked the Parliamentary Secretary to the istry of Food whether he could give figures showing comparable basis, the proportions of eligible children for n parents or guardians were obtaining cod liver oil and juices in the period before April when these were made able to them by the Ministry free of charge, and the nt proportions now that they were available for a small ent —Mr W MABANE replied I regret that it is not ble to supply comparable figures, as the ages of entitle have varied during these periods Also, the products are istributed free of charge to children where the weekly e of the parent(s) or guardian(s) does not exceed certain

From the commencement of the scheme in December, and until Feb 1, 1942, only children under two years were entitled to cod liver oil From Feb 1 to March 31 dren holding R B 2 ration books (i e children under six were entitled to supplies. During the period December ch 31 all children up to two years were allowed fruit ree of charge Payment for the products was intro n April 1, 1942, and supplies of cod liver oil were then ed to children under five years of age From April 1 6 only children under two years were entitled to fruit but as from the latter date the age of entitlement was to three years The figures given below, although cannot be used for purposes of comparison in view of the epancy in the ages of entitlement, give a picture of the up during the periods before and after payment was duced

age weekly take up of		Per cent. of children eligible
d liver oil during four weeks in	March, 1942	24 1

uit juices " " "	March, 1942	38 8
" " " "	June, 1942	33 9

Diphtheria Immunisation

r SMEDLEY CROOKE asked the Minister of Health if, in of the success attending the experiment of sending the ile immunisation service for prevention against diphtheria he children at Portsmouth, he would consider similar ice being sent to children in other cities and large towns re the need for immunisation was equally urgent —Mr WN replied I have already taken steps to ensure that idea is brought to the notice of local authorities generally ny regional officers, and every opportunity is taken of mmending it in areas where it is likely to be practicable useful.—Sir S CROOKE Is the Minister satisfied that there fficient vaccine ?—Mr BROWN We can do the job for the ent —Captain GODFREY NICHOLSON Will the Minister ider the preparation of full sized cinema films which can sed for propaganda ? At present the available films are t suitable for exhibition in an ordinary cinema —Mr OWN I will look into that point

Wing Commander A. W H JAMES asked the Minister ther, since the immunisation of children against diphtheria s available without cost to all parents, he would make an er that the full cost of treatment of diphtheria cases should recoverable from parents in cases where the patients had t been immunised —Mr BROWN replied I do not feel that should be justified in adopting this suggestion

Shortage of Hospital Staffs

Sir R GLYN asked the Minister of Labour what representations he had recently received from the governing bodies of the London voluntary teaching hospitals as regards the position of the hospitals under existing circumstances of increasing work with decreasing staff on account of the continued calling up by his department, whether he was aware that nurses were being overworked as well as the medical staff, that domestic help of the kind and quantity required was not obtainable, and whether he would arrange that the existing staff, both medical and lay, be directed to remain at their posts and that, as far as possible, other essential help would be supplied —Mr ERNEST BEVIN replied I have received no representations from the governing bodies of these hospitals on this general subject and would point out that nursing staff and women domestics in hospitals are regarded as reserved and are not called up by my department and men over military age would not be withdrawn Applications for the deferment of calling up of men of military age are considered individually and no man would be called up until after consultation with the Ministry of Health The selection of medical practitioners for H M Forces is carried out by the Central Medical War Committee subject to the approval of the Minister of Health I am aware of a shortage of nurses and domestic staff in certain hospitals As I have repeatedly stated, nursing and domestic work in hospitals is regarded as vital war work for women of all ages and in addition hospitals themselves can help to meet labour shortage by employing part time domestic workers to the fullest possible extent The whole question of making the best use of the services of hospital staff is under constant review

Hospital Surveys

Mr A PEARSON asked the Minister of Health whether he was aware of the dislike of the contents of his letter dated July 9, 1942, to the chairman of the Nuffield trustees, indicating proposals to organise surveys of local authority hospitals and *that a secret report was to be made to him by the voluntary* organisation on coördination and development of the service in the area the local authority administers, and what indications he had had from Welsh local authorities of their unwillingness for such surveys and secret reports to be made by a voluntary body on their statutory responsibilities —Miss F HORSBRUGH replied The Minister has received no such representations from Welsh local authorities, and the second paragraph of the letter referred to indicates that the Nuffield trustees will undertake surveys only after the representatives of the voluntary hospitals and of the local authorities in the areas concerned have signified their willingness for a survey to be organised

Examination of Women Workers

Lieut -Commander G I HUTCHISON asked the Minister of Labour whether, with a view to preventing women who were not in good health being directed to munition work away from home, he would consider the advisability of arranging that all mobile women should undergo a medical examination before being sent away from their own district —Mr BEVIN replied It is always open to a woman to bring medical evidence to show that she is not fit to undertake employment which is proposed for her, and if necessary arrangements are made for a medical examination As at present advised I do not consider that a routine or compulsory medical examination is desirable

Medical Report on National Flour

Mr ROBERT MORRISON asked the Parliamentary Secretary to the Ministry of Food if he was aware that doctors were prescribing ' Ryvita ' for persons forbidden to eat bread and potatoes, and whether arrangements would be made in these cases to supply this food free of points, or whether the Ministry's medical advisers could recommend an alternative unrationed food —Mr MABANE replied The question of the sensitivity of certain persons to national flour is at present under consideration by the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council and my department is awaiting a report

Saccharin

Mr W J THORNE asked the Parliamentary Secretary to the Ministry of Food if he was aware of a shortage of saccharin tablets which were so valuable to thousands of householders, and if he intended taking any action in the matter —Mr MABANE replied I am aware that there is an unsatisfied demand for saccharin tablets, but as the raw materials are required for more essential purposes I can see no prospect in existing circumstances of increasing the present production, which is about 25 times prewar output

Quinine

General Sir GEORGE JEFFREYS asked the Minister of Supply whether our supplies of quinine were adequate, and, if not, what steps were being taken to replace them.—Mr CHARLES PEAT replied Supplies of quinine are adequate for a considerable period. Active steps have been taken to manufacture synthetic substitutes to replace quinine in the treatment of malaria

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE House is getting more health-conscious A question by Sir Smedley Crooke asking for a mobile immunisation service van for diphtheria to be sent to other cities in view of its success at Portsmouth led to a round of supplementaries like a first-rate political issue Health indeed has become a first-rate political issue

When he announced the completion of the MRC report on tuberculosis the Minister of Health said he had already taken action on a number of points The question, the answer, and the supplementaries occupy more than four columns of Hansard—more than sometimes is given to questions on an important war issue And they
than could get their questions Indeed more members rose
radiography and the acqu stions in The adoption of mass
plus arrangements for the tra ing of 30 sets of apparatus
expert staff is quick action It is to ning of the necessary
provision of the extra accommodation be hoped that the
envisaged by the Minister will not be held up for treatment
nurses *Perhaps the most important provision anno* lack of
by the Minister is the authorisation given to local
authorities to grant financial assistance for the maintenance of the dependants of those undergoing treatment These grants are to be made as part of the public-health service and it will not involve a means test

As to whether these facilities apply to ex-Service men *the Minister was not so explicit as on other points, but it* is clear that an ex-Service man (or woman) is in the same position as any other member of the public The Army do not accept liability for the tuberculosis of men discharged from the Service, unless it is accepted as attributable, which is rare There seems every reason to hope, therefore, that adequate treatment may now become available The Secretary for Scotland, Dr Tom Johnston, was pressed to make a full statement from the Scottish angle but preferred to wait until he had consulted with local authorities

Good as the facilities for diagnosis are, everything turns on the facilities for treatment of early cases and—a matter on which Mr Brown did not touch—on treatment and isolation of advanced cases to prevent the spread of infection A rise in the incidence of tuberculosis occurred in the last war and it occurred in Germany and in Russia as elsewhere The need for tackling the problem today is now so clearly recognised that nothing should be allowed to stand in the way It is hoped that special attention will be given to the ex-Service cases and that the differences *in methods of dealing with cases*, and of accepting financial responsibility for cases, will not be allowed to stand in the way of a nationally efficient system

MINISTER'S STATEMENT ON TUBERCULOSIS

"We are about to begin a new drive against consumption—a drive of a kind never attempted before in this country"

Mr JAMES GRIFFITHS asked the Minister of Health whether he was in a position to make any further statement on tuberculosis —Mr E BROWN replied I am grateful that the committee which was appointed by the Medical Research Council at my request has completed its report which was published on Oct 8 I have kept in touch with the committee and have already taken action on a number of points which are included in their recommendations To facilitate early diagnosis we obtained priority for the supply of some 30 sets of equipment for mass radiography We are allocating them to large centres of population where they can be used to the best advantage In consultation with local authorities and with the assistance of an expert committee we have arranged for the training of the necessary expert staff the operation of this equipment Deliveries will be gradual and arrangements for operation in the individual districts and for cooperation between authorities must be worked out in detail, but I expect that an effective start will be made in the New Year The extended arrangements for diagnosis will mean some increase in the need for accommodation Additional beds are being allocated to meet this need and action is being taken to meet the needs for nursing and domestic staff Domestic and nursing work in hospitals, including sanatoria, is regarded as war service for which suitable women of any age-group may volunteer and to which they may be *allocated by the Ministry of* Labour and National Service, and I have been in consultation with my colleague with a view to special attention to districts where the working of sanatoria is being hampered by a lack of the necessary staff Immediate needs in regard to trained nurses can only be met by a better distribution of the trained nurses available Detailed plans to facilitate *such a distribution and, in particular*, to secure the most effective use of nurses who are completing their training members of the Civil Nursing Reserve, and nurses who can be temporarily spared without prejudice to the current efficiency of the hospital to which they are attached will be worked out by my regional officers in consultation with representatives of the hospitals and of the nurses

Where facilities for diagnosis and treatment are available it is important that those who give up work temporarily *for treatment*, which is in the interest of the public health no less than their own, should be able to do so without financial anxiety as to the maintenance of their dependants Local authorities are accordingly being authorised to grant financial assistance to provide
brea for the maintenance of the dependants and to avoid the
going treatm of the home while the breadwinner is under-
by the public-heal th. This assistance will be administered
treatment under the tuberculosis authorities as a part of the approved
incurred by them in accordan ulosis scheme, and the cost
ments which I am now working out e with detailed arrange-
tives will be repaid from Exchequer t with their representa-
tary of State for Scotland authorises ne funds The Secre-
making similar arrangements in Scotlan e to say that he is

Replying to further questions Mr *Brown* said tha Ministry of Health had under consideration the questi help and encouragement for the after care comm

Mr T JOHNSTON, Secretary of State for Scotland, informed Mr G BUCHANAN that he would make a statement on the scheme as it affected Scotland after he had consulted with the local and health authorities on the subject Mr A MACLAREN asked the Minister if he was not aware that all this expense might be more or less abortive owing to the present bad housing conditions and urged that something must be done immediately to deal with that problem No further reply was given

QUESTION TIME

Cod-liver Oil and Fruit Juices for Children

Mr H BROOKE asked the Parliamentary Secretary to the Ministry of Food whether he could give figures showing on a comparable basis, the proportions of eligible children for whom parents or guardians were obtaining cod liver oil and fruit juices in the period before April when these were made available to them by the Ministry free of charge, and the present proportions now that they were available for a small payment —Mr W MABANE replied I regret that it is not possible to supply comparable figures, as the ages of entitlement have varied during these periods Also, the products are still distributed free of charge to children where the weekly income of the parent(s) or guardian(s) does not exceed certain limits From the commencement of the scheme in December, 1941, and until Feb 1, 1942, only children under two years of age were entitled to cod liver oil From Feb 1 to March 31 all children holding R B 2 ration books (i e children under six years) were entitled to supplies During the period December to March 31 all children up to two years were allowed fruit juices free of charge Payment for the products was introduced on April 1, 1942, and supplies of cod liver oil were then restricted to children under five years of age From April 1 to July 6 only children under two years were entitled to fruit juices, but as from the latter date the age of entitlement was raised to three years The figures given below, although they cannot be used for purposes of comparison in view of the discrepancy in the ages of entitlement, give a picture of the take up during the periods before and after payment was introduced

Average weekly take up of		Per cent of children eligible
Cod liver oil during four weeks in	March, 1942	24 1
” ” ” ”	June, 1942	12 8
Fruit juices ” ” ”	March, 1942	38 6
” ” ” ”	June, 1942	33 9

Diphtheria Immunisation

Sir SMEDLEY CROOKE asked the Minister of Health if, in iew of the success attending the experiment of sending the obile immunisation service for prevention against diphtheria the children at Portsmouth, he would consider similar rvice being sent to children in other cities and large towns here the need for immunisation was equally urgent —Mr ROWN replied I have already taken steps to ensure that is idea is brought to the notice of local authorities generally my regional officers, and every opportunity is taken of commending it in areas where it is likely to be practicable d useful —Sir S CROOKE Is the Minister satisfied that there sufficient vaccine ?—Mr BROWN We can do the job for the oment —Captain GODFREY NICHOLSON Will the Minister nsider the preparation of full sized cinema films which can used for propaganda ? At present the available films are ot suitable for exhibition in an ordinary cinema —Mr ROWN I will look into that point

Wing Commander A. W H JAMES asked the Minister ether, since the immunisation of children against diphtheria as available without cost to all parents, he would make an der that the full cost of treatment of diphtheria cases should recoverable from parents in cases where the patients had ot been immunised —Mr BROWN replied I do not feel that should be justified in adopting this suggestion

Shortage of Hospital Staffs

Sir R GLYN asked the Minister of Labour what representations he had recently received from the governing bodies of the London voluntary teaching hospitals as regards the position of the hospitals under existing circumstances of increasing work with decreasing staff on account of the continued calling up by his department, whether he was aware that nurses were being overworked as well as the medical staff, that domestic help of the kind and quantity required was not obtainable, and whether he would arrange that the existing staff, both medical and lay, be directed to remain at their posts and that, as far as possible, other essential help would be supplied —Mr ERNEST BEVIN replied I have received no representations from the governing bodies of these hospitals on this general subject and would point out that nursing staff and women domestics in hospitals are regarded as reserved and are not called up by my department and men over military age would not be withdrawn Applications for the deferment of calling up of men of military age are considered individually and no man would be called up until after consultation with the Ministry of Health The selection of medical practitioners for H M Forces is carried out by the Central Medical War Committee subject to the approval of the Minister of Health I am aware of a shortage of nurses and domestic staff in certain hospitals As I have repeatedly stated, nursing and domestic work in hospitals is regarded as vital war work for women of all ages and in addition hospitals themselves can help to meet labour shortage by employing part time domestic workers to the fullest possible extent The whole question of making the best use of the services of hospital staff is under constant review

Hospital Surveys

Mr A PEARSON asked the Minister of Health whether he was aware of the dislike of the contents of his letter dated July 9, 1942, to the chairman of the Nuffield trustees, indicating proposals to organise surveys of local authority hospitals and that a secret report was to be made to him by the voluntary organisation on coördination and development of the service in the area the local authority administers, and what indications he had had from Welsh local authorities of their unwillingness for such surveys and secret reports to be made by a voluntary body on their statutory responsibilities —Miss F HORSBRUGH replied The Minister has received no such representations from Welsh local authorities, and the second paragraph of the letter referred to indicates that the Nuffield trustees will undertake surveys only after the representatives of the voluntary hospitals and of the local authorities in the areas concerned have signified their willingness for a survey to be organised

Examination of Women Workers

Lieut -Commander G I HUTCHISON asked the Minister of Labour whether, with a view to preventing women who were not in good health being directed to munition work away from home, he would consider the advisability of arranging that all mobile women should undergo a medical examination before being sent away from their own district —Mr BEVIN replied It is always open to a woman to bring medical evidence to show that she is not fit to undertake employment which is proposed for her, and if necessary arrangements are made for a medical examination As at present advised I do not consider that a routine or compulsory medical examination is desirable

Medical Report on National Flour

Mr ROBERT MORRISON asked the Parliamentary Secretary to the Ministry of Food if he was aware that doctors were prescribing 'Ryvita' for persons forbidden to eat bread and potatoes, and whether arrangements would be made in these cases to supply this food free of points, or whether the Ministry's medical advisers could recommend an alternative unrationed food —Mr MABANE replied The question of the sensitivity of certain persons to national flour is at present under consideration by the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council and my department is awaiting a report

Saccharin

Mr W J THORNE asked the Parliamentary Secretary to the Ministry of Food if he was aware of a shortage of saccharin tablets which were so valuable to thousands of householders, and if he intended taking any action in the matter —Mr MABANE replied I am aware that there is an unsatisfied demand for saccharin tablets, but as the raw materials are required for more essential purposes I can see no prospect in existing circumstances of increasing the present production, which is about 25 times prewar output

Quinine

General Sir GEORGE JEFFREYS asked the Minister of Supply whether our supplies of quinine were adequate, and, if not, what steps were being taken to replace them —Mr CHARLES PEAT replied Supplies of quinine are adequate for a considerable period. Active steps have been taken to manufacture synthetic substitutes to replace quinine in the treatment of malaria

Medical News

University of Cambridge

At recent examinations the following were successful

DMRE

Part II—R A D J Bernhardt, A B Donald, H R Holmes, Benzion Kounine, Arnost Preiss, R A Williams and Hugh Wormald

Royal College of Surgeons of England

At a meeting of the council of the college, held on Oct 8, with Sir Alfred Webb Johnson, the president, in the chair it was decided to increase the membership of the court of examiners from 17 to 20 Mr A J Graham was nominated as the fiftieth Jenks scholar A Leverhulme scholarship was awarded to F K Sanders, D Phil, who is investigating problems connected with the repair of peripheral nerve injuries Dr Douglas Lea was nominated for reappointment and Dr Lilian Walter for appointment as Prophit students for cancer research Mr Geoffrey Bourne, D Sc, has been reappointed a Mackenzie Mackinnon research fellow

Diplomas of membership were granted to T D Kellock, H G McQuade, J R K Preedy, D S Short, Edith M Waterhouse, and J F R Withycombe Diplomas in child health were granted jointly with the Royal College of Physicians to the following

A P Bentall, Elliott Emanuel, E G Fox J F Galpine, Aitolia Georgiadis, Margaret E Harker, D C Jackson, Elizabeth B S Scobbie, and Vera Settle

Society for Relief of Widows and Orphans of Medical Men

At a quarterly court on Oct 7 Dr R A Young, senior vice president, being in the chair, respect was paid to the memory of Mr V Warren Low, president for thirteen years The accounts for the half year ended June 30 were approved, grants to widows during this period came to £1937 10s, and £2090 had been invested After being for some years in abeyance, it was decided to make a Christmas present this year of £7 10*s* to each widow in receipt of a grant Membership of the society is open to any registered medical man residing within a twenty mile radius of Charing Cross Particulars from the secretary, 11, Chandos Square, London, W 1

Royal Medico-Psychological Association

A meeting of this society will be held at 10 30 AM, on Wednesday, Oct 21, at 11, Chandos Street, London, W 1, when there will be a symposium on the incidence of tuberculosis and dysentery in mental hospitals

Institute of Chemistry

The South Yorkshire section will hold a special meeting on the chemist and industrial health at Sheffield city hall on Thursday, Oct 22, at 2 45 PM Dr F S Fowweather and Dr M W Goldblatt are to be the opening speakers Further information from the hon secretary of the section, at 52, Whirlow Grove, Sheffield, 11

Photography in Industry and Science

During November the Association of Scientific Workers is promoting an exhibition illustrating this title which will include work on mass radiography and nuclear physics Sir Robert Watson Watt, FRS, will open the exhibition on Oct 13, at 3 PM, in the rooms of the Royal Photographic Society at 16, Prince's Gate, London, SW7

North Western Tuberculosis Society

A meeting of this society will be held at 3 PM on Thursday, Oct 22, at the tuberculosis offices, 352, Oxford Road, Manchester, when Wing Commander R R Trail will speak on mass miniature radiography

Chadwick Lecture

On Tuesday, Oct 27, at the Royal Sanitary Institute, 90, Buckingham Palace Road, London, SW1, Mr W T Creswell, KC, will give a Chadwick lecture on the forensic aspects of war time public health legislation

RAMC Casualties

WS/Captain R J F Howe, MRCS, previously reported prisoner, is now posted as wounded and prisoner Major M E M Herford, MBE, MB Brist, has been wounded and the following officers have been taken prisoner Captain William Falconer, MB Edin, Lieut Colonel J T Lewis, FRCP, and Major J W Redgate, MRCS

Royal Society of Medicine

A meeting of the fellows of this society will be held on Tuesday, Oct 20, at 5 PM At 2 30 PM on the same day there will be a discussion at the section of orthopædics on painful feet The openers are to be Mr C Lambrinudi, Dr E J Crisp and Mr H L C Wood At 2 30 PM, Oct 21, at the section of comparative medicine, Prof Alexander Fleming, Mr A T Glenny and Mr Percival Hartley, FRS, will open a discussion on active immunity The urology section is holding a clinico pathological meeting on Oct 22, at 3 45 PM Dr Helen Mackay, Dr Leonard Findlay and Dr Hugh Sinclair are speaking at the section of disease in children on Oct 23, at 2 30 PM, when there is to be a discussion on nutritional anæmia in children and women as a war time problem

Dietetic Course for Nurses

The Royal College of Nursing has organised a dietetic course for nurses which will include 240 hours of practical experience in the dietetic departments of the Hammersmith Hospital, the London Hospital and in the canteen of the Morgan Crucible Company There will also be lectures on chemistry, physics, biochemistry and physiology Food for the sick, the healthy and the infant will be discussed and there will be lectures on the new dehydrated foods and on war time deficiencies to be guarded against in communal feeding Further particulars may be had from the director of the education department of the college, Henrietta Place, London, W 1

The Index and title-page to THE LANCET, Vol I, 1942, which was completed with the issue of June 27, is now ready A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Births, Marriages and Deaths

BIRTHS

BANKOFF—On Oct 7, the wife of Mr George Bankoff, FRCS, of Harley Street, W 1—a son

BARCLAY—On Oct 3, at Devonport, the wife of Dr Gordon Barclay—a daughter

GORDON GRAY—On Oct 1, in Aberdeen, the wife of Major Stuart Gordon Gray, RAMC—a daughter

GREENE—On Oct 6, at Sutton, Surrey, the wife of Lieutenant A C Greene, IMS—a daughter

LEVICK—On Oct 5, at Windsor, the wife of Lieutenant R K Levick, RAMC—a daughter

MANNING—On Oct 3 at Farnborough, the wife of Dr F R C Manning, RAFVR—a daughter

NICHOLSON—On Oct 6, at Sutton Coldfield, the wife of Mr J C Nicholson, FRCSE, RAMC—a daughter

NORMAN—On Oct 6, at Poole, the wife of Surgeon Lieutenant R T Norman, RNVR—a daughter

ORAM—On Oct 5, the wife of Lieutenant Sam Oram, RAMC—a daughter

ROBINSON—On Oct 2 in Glasgow, the wife of Captain Wilfred Robinson, RAMC—a daughter

WAR AND THE ADVANCEMENT OF SOCIAL MEDICINE*

SIR WILSON JAMESON M D ABERD, LL D, F R C P, D P H
CHIEF MEDICAL OFFICER TO THE MINISTRY OF HEALTH AND BOARD OF EDUCATION

MOMENTOUS happenings such as those that marked Harvey's lifetime have often been followed by periods of great social change, and today I would recall some of the more modern lessons of war in the evolution of social medicine.

The great wars of the Napoleonic times are naturally the first to which we turn. This period was ultimately followed by a great stabilising advance in Europe, the seeds of which, so far as this country was concerned, were sown far back in the eighteenth century. The Industrial Revolution (1760) first made manifest the magnitude and character of the modern social problems. The Declaration of American Independence (1776) and the French Revolution (1789) announced to all the world a new conception of the political rights of man. In 1776 Adam Smith's *Wealth of Nations* and Jeremy Bentham's *Fragment on Government* established the fundamental economic and political principles of reform. The immediate reaction of our own politics to the Napoleonic wars was a static period, but the ideas sown long before had taken firm root and, strengthened by the fall of old-established but decrepit institutions, produced their effects during succeeding generations. There were the first Factory Acts, the initial grand experiment of defining the conditions that led to the recognition of industrial disease and the means of prevention. There was the humanitarian abolition of slavery in the British Empire, and there was the introduction of elementary education and the social emancipation brought about by the reform first of parliament and then of the poor law and the municipal corporations.

Nor did these constructive political principles stand alone, for even more arresting and threatening was the invasion of Britain by cholera in 1831, which led to the temporary establishment of cholera dispensaries and local boards of health and the emergence of that eminent pioneer Edwin Chadwick (the friend of Bentham), secretary of the Poor Law Commission, and maker of the first Board of Health in central government. Cholera came four times in epidemic form between 1831 and 1866, and served as a solemn warning to England to put her house in order.

CRIMEAN WAR

The period of the Crimean War (1854–56) marked another great awakening of the British mind. Professor Trevelyan of Cambridge has declared that "the real hero of the war was Florence Nightingale, and its indubitable outcome was modern nursing, both military and civil, a new conception of the potentiality and place in society of the trained and educated woman." Herbert Fisher in his *History of Europe* (1936) said that Miss Nightingale by "her personal example and fiery energy then and thereafter raised the whole status of the nursing profession, improved the standard of public hygiene, and, more powerfully perhaps than any other single influence, won for the women of her country the right of entry into serious and useful callings. The extraordinary achievement of Florence Nightingale in defying the conventions of the age in her great work for the relief of human suffering is one of the few compensations for the waste and havoc of the Crimean War."

Her example and energy were no doubt important factors in her historical contribution to social medicine. But her extraordinary powers of mind, knowledge, and genius were even more material and fruitful. In the Crimea Miss Nightingale opened wide the gates of order and efficiency in place of disorder and neglect. She broke through the tortuous ramifications of administrative incapacity, confusion and divided responsibility in the military hospitals; in place of the ignorance, incompetence and ineptitude of red-tape officialism she brought exact knowledge, experience and commonsense, and thus abolished the complacent acquiescence in a high mortality from wounds and a still higher mortality from preventable disease and starvation. In fact she reduced the mortality from disease among the soldiers by two-thirds.

After two dramatic years in the Crimea Miss Nightingale faced her next problem—the lack of hygiene in the British Army. In 1858 she published her *Notes affecting the health, efficiency and hospital administration of the British Army*. The Royal Commission appointed in 1857 to inquire into the sanitary condition of the army set a high value on her interesting evidence and it was largely due to her influence that an army medical college was opened at Chatham in 1850, a military hospital built in Woolwich in 1861 and an army sanitary commission established in permanence in 1862. Second, came the far-reaching problem of the necessity for adequate training of nurses, the institution of the Nightingale Training School, and the creation of a nursing profession. As a prelude thereto she published in 1859 her popular and classic *Notes on Nursing; what it is and what it is not*. Her third task was the initiation of a Royal Commission on the Sanitary State of the Army in India (1863). This dealt with the reorganisation of the public-health system in India, including sanitary commissioners, sanitation of villages, land irrigation, hospitals and prisons, and the prevention of periodic famines. Fourthly, in 1861 Miss Nightingale coöperated with Mr William Rathbone of Liverpool in introducing trained nurses in poor-law institutions in place of untrained "pauper nurses." Thus she created the special course of training and the wider sphere for nurses, midwives and health visitors. Lastly, in August, 1861, Miss Nightingale at the request of the British War Office formulated for the Geneva Convention the terms of the declaration of the principle of the "neutralisation" in war of Red Cross hospitals, doctors, nurses and wounded soldiers of whatever nation or race. These are the elements of Miss Nightingale's extraordinary workmanship and incomparable public service, so varied and skilful and prolonged over the immense period of her lifetime of ninety years. But it was of such national and international importance that historians agree that it changed the social history of England.

It is also instructive to recall that at this exact time the British Government taught the world the practice of preventive medicine, when Sir Edwin Chadwick, Lord Shaftesbury and Sir John Simon used to good purpose what they called the "new momenta"—growth of altruism in politics, increased consideration for the units of mankind, a developed apprehension of the meaning of social justice, and a widened consciousness of the range of social duty. Each in its application to hygiene and sanitary environment effected "a quickening time of human history, the new humanity promoting the rise of state medicine in England." From that were generated the Poor Law and the Health of Towns Commissions, the first great Public Health Act, affecting sanitary environment, a central Board of Health in Whitehall, the local medical officer of health, the General Register Office, and special legislation for the medical profession. Not a whit less important historically in its day was the Education Act of 1870, which first required elementary education of the English children, as well as the Royal Sanitary Commission of 1869–71, consolidating forty years of health legislation in the Public Health Act of 1875. These were the fundamental bases of national health which prepared the nation for a renaissance of reform in the governance of England in 1906.

SOUTH AFRICAN WAR

It seems rather strange that this new birth was ushered in by the effects of the South African (Boer) War. This was not one of the principal wars that change the affairs of men, but it touched the modern idealism in England very intimately. It raised from the beginning far-reaching issues concerning Imperial expansion. The Boers viewed it as a war of independence, the British Government saw it as the hopeful occasion for colonisation and empire consolidation. But alas, an ultimatum was issued, foresight was sadly lacking, and guerilla methods dragged the war on unexpectedly. Another complication was the disaster arising from the establishment by the British of "concentration camps" for Boer women and children which were so mismanaged that appalling mortality resulted. This had far-reaching political repercussion in England, as had the fact that upwards of 14,000 British soldiers died from disease, chiefly enteric fever, as against some 8000 who were killed in battle or died of wounds. The war ended on May 31, 1902, and the subsequent terms of peace were generous—repatriation, grants in aid of rebuilding, and self-government for Boers and British alike. Yet the problem of the physical unfitness of many army recruits, of the high mortality among the women and children in the Boer concentration camps, and the excessive mortality of the soldiers from disease were three facts that awakened England to the urgency and gravity of certain matters affecting the national health. The preventable loss of life profoundly impressed the British public and roused it to action.

* Harveian oration delivered before the Royal College of Physicians of London on Oct 19, 1942.

The first fruits in England of the social effect of the South African War are to be found in the remarkable reports of three official inquiries.[1] For it was these three independent official "inquests" that for the first time in our national history brought to the notice and arbitrament of public opinion such homely domestic matters as the feeding, physical training and medical supervision of school-children in Britain. These reports created a profound impression on the heart and mind of the public and marked the birth of modern social medicine in this country. Not for thirty years had there been anything comparable with their effect, and the demand for social change was voiced in the new Parliament of 1906, which recognised that the children were the kernel of "the condition of the people question," and required an adequate national standard of health and decent living. These reports furnish a clear contrast with the famous report of the Royal Sanitary Commission of 1871, which dealt with the policy and administration of the health and sanitary system, while the new movement concerned the personal health, capacity and fitness of the individual. Let me name the purposes as they appeared in the Parliament of 1906:

> School feeding of children in attendance at elementary schools, school medical inspection and treatment, school care committees, prevention of infection in schools, physical training and hygiene in the school code, choice of employment for children, the early notification of births for the health visitation of every child, the campaign for the prevention of infant mortality, schools for mothers, the admission of elected women members to county and county borough councils, the provision out of the local rates of recreational open spaces, workmen's compensation for accidents in factories, old age pensions, labour exchanges, housing and town planning and the National Health Insurance Act of 1911.

All this was a novel "unheard of before" business, which engendered immense discussion and public controversy in Parliament and in every home in the land. Parliament had never in its history come so close to the homelife of the people of England for these social, even domestic, questions had not been hitherto the subject of statutory law. For here is the social purpose of some eighteen new laws in six years, conjoint evidence of a new spirit in the evolution of a people and its own governance, the very foundation-stones of social medicine.

The next ten years enhanced and extended the public interest awakened by these bills, and for the simplest of all reasons, a harvest of result was being gathered in—in every district, in every school, almost in every family—affecting the people's food, exercise, medical supervision, health, leisure, security. Life itself had been saved, or assured, or extended and enlarged. It was indeed a turning point to better and brighter days. What had brought this about ?

Of course so great a movement could be the result only of a long ancestry of causes. Many changes had marked England since the beginning of the industrial revolution in the middle of the eighteenth century. Not the least of these were the new humanitarianism typical of which were the Methodist Revival and the lives of John Howard, Edmund Burke, Wilberforce, Robert Owen, Romilly; the monetary value of health and life as contrasted with the monetary value of industry; the Reform Bill and the Ten Hours Bill agitation; the Public Health and Education Acts; the always extending enfranchisement; an always expanding British Commonwealth; and the evolution of democracy through a local government system, in which social cooperation and collectivism won victories impossible to despotic rule. All these belong to the ancestry of causes. But there was another kind of ferment coming into active operation—the growth of science, discovery and knowledge with its consequent new power, and particularly the ever widening influence of the scientific method. It was the application of the scientific method to the study of social conditions that resulted in the publication from 1889 to 1902 of a book on the *Life and Labour of the People of London*, by the Rt Hon Charles Booth, what he called "The Grand Inquest."

Charles Booth, modern interpreter of sociological science, was a shipowner of Liverpool. His scientific temperament and curiosity led him to study the structure and working of human society in London. His practical ideal was faith in the scientific method combined with altruistic service to man. Sound reason, a good conscience, will power and energy inspired his inquiry into the unsatisfactory social conditions obtaining amongst the poor, attributed variously to improvidence, ineptitude, self-indulgence or "original sin." Booth did not agree and asked himself: How do the people really live, and what is it they really want, or need, to render decent existence practicable ? Thus his exploration began in 1886, aided by a small army of school-attendance officers and other home visitors, and ended in seventeen volumes, a Domesday Book of the people of London at the dawn of the twentieth century. We all know that he found thirty per cent living at or below the level of bare subsistence, a condition leading inevitably to degeneration of body and mind. He also found that the Poor Law and Charity Organisation were inadequate remedies, but that collective organisation was a more likely one, while compulsory education up to adolescence, state labour exchanges, health and unemployment insurance, and old-age pensions might resolve the problem. He set to work accordingly and this historic book provided irrefutable evidence of the need for a social "national minimum" of subsistence and for collective efficiency, control, discipline and governance.

The evolution of social thought in the nineteenth century, to which Charles Booth's great work was such a splendid contribution, was well described in 1910, in the twelfth volume of the Cambridge Modern History:

> "The change that has come over the civilised world may be summed up in a phrase. What may be called our 'atomic' view of human society has been replaced by a more 'organic' conception. Three quarters of a century ago the dominant social philosophy was that of *laissez faire*. Though in England and some other countries arrangements were made to keep the starving from death, and to prevent actual brigandage and robbery by violence, what little collective action existed was undertaken grudgingly, and by way only of exception. The community as a whole assumed no responsibility for the individual. The pressure upon his will produced by the free competitive struggle would, it was assumed, if only 'let alone,' result in the utmost possible development of human happiness and human faculty. The current ideal of the social order was that of a congestion of warring atoms, the free competition of which would, it was quite confidently assumed, unconsciously result in the best attainable social state. The unit, it was said, was the family group, by which was meant, in practice, the male head of the family, the wife and children being scarcely recognised by the law as human beings, with rights and interests independent of those of the dominant adult male. By the beginning of the twentieth century we find an altogether different conception of society. The unit is no longer the family group, but the individual human being, whether newly born infant, child, adolescent, adult woman or male head of the household. And we no longer believe that 'beneficent private war' necessarily secures public ends."

FIRST WORLD WAR 1914–18

And so we come to the first World War. Its effect on the progress of social medicine was profound. The destruction of our young manhood made manifest the need to save life wherever possible, so in 1915 notification of births to the local medical officer of health was made compulsory and child welfare schemes officially inaugurated. Three years later the powers given to local authorities to provide means for the safeguarding of the health of mothers and infants were stabilised and extended. At the same time the medical inspection of all children attending secondary and continuation schools was introduced and the treatment of defects found in elementary school-children, till then optional on the part of local education authorities, was made compulsory. A scheme for the early diagnosis and treatment of venereal disease—made necessary by the great increase in the number of sufferers—was introduced in 1916 and in most areas the work was undertaken by voluntary hospitals with financial help from the Government and the major health authorities. In the same year welfare work in industry was given proper recognition and powers were granted to require its introduction in selected factories where the need was greatest. As soon as might be after the signing of the armistice Parliament created a Ministry of Health "for the purpose of promoting the health of the people throughout England and Wales," and the hopes of Sir John Simon and his fellow workers in the second half of the preceding century were thus finally realised. The changes in central medical administration consequent on the establishment of the new Ministry were not, it is true, so far-reaching as many desired but the step taken by Government was full of significance. Who can say what further changes may be effected as the outcome of this war?

---

[1] The Royal Commission on Physical Training (Scotland) in 1903, the Interdepartmental Committee on Physical Deterioration in 1904, and a Departmental Committee on Medical Inspection and the Feeding of Children attending Public Elementary Schools in England, in 1905.

Shortly before the last war there had been established under the National Health Insurance Act a Medical Research Committee. In its origin it was designed to forward the objectives of insurance, but its admirable secretary, the late Sir Walter Fletcher, turned it at once to the medical emergencies of war with the result that it became truly national in its application and effect. This prompt opportunist application to the immediate medical necessities of the war had a touch of real genius about it, for it demonstrated that the design of this new research organisation was no merely academic study in abstract science but a living and dynamic power-house for the saving of human life. In the re-ordering of affairs that was inevitable after the war this committee became the Medical Research Council and its control was placed in the wise hands of the Lord President of the Privy Council, thereby freeing it from technical departmental interference and giving its sphere of operation boundaries no less wide than those of the British Empire itself. The Health of Munition Workers Committee, appointed in 1915 under the chairmanship of one of my distinguished predecessors in office, Sir George Newman, made a great contribution to the well-being of workers in factories and after the war became part of the Medical Research Council's organisation under the new title of the Industrial Health Research Board. Its findings regarding fatigue are as true now as they were twenty-four years ago and there is urgent need for their more general application.

BETWEEN WORLD WARS

The increase in tuberculosis that occurred in the last war made obvious the necessity of dealing with this disease as a national problem rather than as one for special attention among insured persons under the heading of "sanatorium benefit." Accordingly in the immediate post-war years the major local authorities were required to make adequate provision for the diagnosis and treatment of all sufferers from this great social disease. Again, as a result of the war there was an acute shortage of housing accommodation, so Government took an active part in stimulating building in every part of the country. Efforts were directed at first to make good the shortage of houses without much regard to the worst housed members of the community. Before long, however, the real public-health implications of housing came to be realised as never before and this country embarked on a programme of slum clearance and of rehousing the poorest of the people that, whatever its shortcomings, has been of inestimable benefit to health. Nor did social reform stop at this point. Discontent with the operation of the old poor law had been frequently expressed and change was inevitable. Under the late Mr Neville Chamberlain's guidance a sweeping measure of reconstruction was passed through Parliament in 1929 whereby our century-old boards of guardians, in themselves a great improvement on what had gone before, were swept away and their functions transferred to the councils of the counties and county boroughs. Thus the coordination of public health and of public assistance was brought about and the creation of a national hospital system, based on the fusion of voluntary and of local government effort, was made possible.

In the meantime medical education had not stood still though the changes introduced tended rather to complicate than to simplify the lot of the struggling undergraduate. The beginnings of two noteworthy movements may be detected in this connexion. First of all an insistent demand began to be made for the introduction of what has been called "the preventive outlook" into the medical curriculum and in the second place postgraduate education at last received visible recognition in the establishment of the two great London centres—the London School of Hygiene and Tropical Medicine and the British Postgraduate School. The influence of these two institutions, and still more of the currents that led to their appearance among the schools of the University of London, has yet to be realised.

Lessons of this War

What will be the probable effect on the progress of social medicine of the ordeal through which the world is now passing? So many nations are suffering in common in these days of trial that it is unthinkable they should not share in common whatever good the future holds in store. Of all the efforts to further international cooperation that followed the last war none achieved greater success than that made in the field of public health and the advancement of medical knowledge. Who can doubt that the same will still be true when these tragic events have spent themselves. But it is rather on the influence of the war years on our own people that I would dwell today, and here one can detect a marked difference, so far at any rate as the feelings of the medical profession are concerned, between this war and the last. Most of us who served in the period 1914–18 can recall how we looked forward to the time when we should return to the kind of life we had been leading before enlistment, to the practices or the appointments we had left, eager to get back to things as we knew them before the war clouds burst. Not so in this war. There is everywhere a conviction that great changes lie ahead of us and a desire so to plan the measures designed to meet the national emergency that some permament good may be derived from them when the world is once again at peace.

In the past we have prided ourselves on our adherence to precedent and on the gradual evolution of our schemes of social reform. Let me remind you of Tennyson's definition of England:

"A land of settled government,
A land of just and old renown,
Where Freedom slowly broadens down
From precedent to precedent;

Where faction seldom gathers head,
But by degrees to fullness wrought
The strength of some diffusive thought
Hath time and space to work and spread."

This may have been true in the spacious days of the nineteenth century, but is it true today? With the advances that have been made in human knowledge in recent years can we afford to proceed from precedent to precedent, and does not diffuse thought work and spread with a velocity undreamt of even a generation or two ago? We have to ask ourselves whether the speed at which we have lately been living can ever again be slowed down even to the prewar tempo; whether much of the liberty to which we used to refer with pride was not in fact rather a licence to disregard the effects of many of our acts of commission or of omission on the well-being of others; and whether a people that has experienced such an upheaval in its ways of living and of thinking will ever desire to return wholly to its former habits. There has been the most grave interference with the liberty of the subject, liberty of labour, liberty of movement, liberty of property and liberty to buy and sell even the most ordinary commodities of life, all of which has been accepted with hardly a murmur, rather at times with acclamation. We have indeed learned what the people of these islands will endure gladly under wise and courageous leadership It may be that some extensive programme of social reform, of which social medicine would be an integral part, will be introduced as an immediate post-war measure Who can say? For war, though a great destroyer of things worth preserving, may yet, almost overnight, open the door to progress and reform that in other times would have cost years of constant striving

HOSPITALS AND LABORATORIES

And so, in attempting even in the most general terms to indicate the nature of possible post-war changes, may I direct your attention to some of the far-reaching measures that have been adopted to meet the medical needs of the state of emergency that has already lasted for more than three years

First of all there has been developed throughout England, Scotland and Wales an Emergency Hospital Scheme Broadly, this scheme consists of utilising, improving and supplementing existing hospitals, which continue to be independently administered by their owning authorities, voluntary or municipal, and the majority of which are still concerned with their ordinary work among the local sick as well as with patients who fall within the scheme The Emergency Medical Service is the name given to the body of medical men and women enrolled and paid by Government for service under the emergency hospital arrangements

The scheme may be full of faults—those most intimately associated with it are the most ready to admit its defects—but it can, and does, accept responsibilities that neither the profession nor the hospitals in their former condition as a series of isolated units could ever have undertaken It has shown the value of linking together the various hospitals in regions of which the vital centres are the great medical schools And it is not merely the hospital administration that has been coordinated in this fashion, much more important has been the organisation of the medical staffs that has been brought about Consultants have been redistributed and their services made available in many places where such provision had formerly been wholly inadequate Voluntary hospitals and local authorities' hospitals have entered into the closest sort of association Some of our teaching hospitals are the welcome guests of institutions belonging to local authorities and are learning what a wealth of valuable teaching material they have gained thereby The medical staffs of local authorities, on the other hand, have come to realise how much they benefit from day to day contact with their colleagues from the teaching hospitals Many more whole-time appointments have been created in hospitals and in these appointments large numbers of medical men and women have found the opportunities they desired but which were denied them in the past It has been found possible in this scheme of hospital organisation to bring together in selected institutions cases of injury or disease requiring specialised forms of treatment, and thus we have got centres for plastic surgery, for neurosurgery, for head injuries, for rehabilitation and for neuroses Various methods of treatment, too, can be tried out on a grand scale and an estimate of their value obtained much more readily than would have been possible in prewar days Finally, many of the institutions themselves have been improved out of all recognition—"upgraded" in official jargon; operating theatres have been provided, additional wards have been built, fresh equipment has been installed Indeed, the Ministry of Health has itself added no fewer then forty-seven thousand beds to the total of those already provided by voluntary agencies and local government authorities From being a service originally designed to secure the treatment of service sick and of battle and air-raid casualties the Emergency Hospital Scheme has come to care for the medical needs of large groups of the civilian population—workers in war-time industries, evacuees of all sorts persons engaged in the various branches of civil defence and many others Fortunately we have not been called upon as yet to care for battle casualties on any very large scale and the hospital beds have therefore been placed at the disposal of the civilian population so far as has been found practicable One important result has been the virtual disappearance of many hospitals' waiting-lists

Laboratory services, confined in former days almost wholly to a few main centres throughout the country, had obviously to be greatly augmented to meet the needs of the emergency hospitals on the one hand and to deal with outbreaks of epidemic disease on the other During 1939 a scheme for an emergency public-health laboratory service was worked out in great detail and, a day or two before war was declared, staff and equipment were transferred to selected centres in England and Wales Each unit was ready to start work when the day arrived This epidemiological service, organised and managed by the Medical Research Council on behalf of the Ministry of Health, has been of the greatest help Skilled public-health laboratory workers are posted at key points throughout the country, able and willing not only to undertake the necessary technical laboratory procedures but also to go out into the field and assist in the control of outbreaks of disease and, better still, in the carrying out of large scale programmes of immunisation I hope this combination of bench work and field work will become a permanent part of our armamentarium against infectious disease In this work we have been helped in the most generous and skilful fashion by the American Red Cross-Harvard Field Hospital Unit, which with its association of wards, laboratories and teams of doctors and public health nurses has shown us the way in which epidemiological knowledge can best be applied in the study and control of outbreaks of infectious disease May I say, at this point, that this unit represents by no means the only medical war-time debt we owe to our professional colleagues in North America Our hospital pathological services have been similarly extended and, I hope, a closer association between clinicians and pathologists thereby established The days of a purely postal laboratory service are surely ended and, I trust, the hospital pathologist will have as useful a place in the ward and outpatients department as the public health bacteriologist in the school, the clinic, the residential nursery and the homes of the people

INFECTIOUS DISEASE

Great progress too has been made in protecting the children of this country against diphtheria Before the war efforts in this direction were haphazard and spasmodic but at the end of 1940 the Government undertook to issue free of charge to all local authorities an approved prophylactic against diphtheria This gave the necessary fillip to the movement for the control of this pernicious disease and since that date some three million children under fifteen have been dealt with under official schemes The numbers are not nearly large enough, but they are growing and we have as a goal before us the wonderful achievements of some of the great cities in Canada and the United States where diphtheria has become so rare a disease that difficulty is experienced in finding sufficient cases for the teaching of medical students Trials of a vaccine against whooping-cough are being conducted by the Medical Research Council and it may be that before long we shall find we have forged a weapon against one of the most fatal infectious diseases in very young children

A war-time increase in the incidence of tuberculosis was foretold and the forecast was unfortunately only too accurate The increase has made necessary a review of our methods of dealing with this disease—one of the greatest of all problems of social medicine The actual prevention of tuberculosis can be achieved only by a long and continuous attack on a number of social evils Our aim must be to secure higher standards of living, more satisfactory conditions of work, better housing, safe milk We can, however, seek to ensure the next best thing to actual prevention and that is the detection of the disease in its earliest and most treatable stages This is what we hope to do in the course of time by the wise use of the cheap, rapid and reliable methods of miniature radiography The part such methods can play must not be over-estimated, but that they can do much to sort out the cases that require further examination can hardly be denied Fortified by this belief the Ministry of Health has itself undertaken to see that as many sets of apparatus as possible are made available during war-time, and it is hoped that they will be put to good use by the profession Early detection by itself is hardly enough There must be adequate institutional accommodation for those who need it, reasonable maintenance for the family whose wage earner is undergoing treatment and a wisely planned scheme of rehabilitation recognised as an essential part of treatment itself. The need for a comprehensive scheme of this nature has been stated by the Minister of Health in the House of Commons and an effort will be made to put into operation such parts of it as existing conditions permit. The active support of the whole of the medical profession will be necessary if success is to be achieved.

NUTRITION

Another problem thrown into prominence by the war has been the maintenance of a satisfactory standard of national nutrition. It must be admitted that in the past, attempts to induce the people of this country to adopt a more health-giving dietary have not proved very successful. The creation of a Ministry of Food and the placing of the control of all foodstuffs in the hands of the Minister have, however, changed all this. There is now cooperation between the State Departments of Health, Food and Agriculture. The Cabinet has decided that it is the duty of the Minister of Health to advise on nutritional policy and that it is the business of the other two ministries, so far as is practicable, to give effect to this policy either by importing or by producing the foodstuffs required. Huge sums have been spent by the Ministry of Food on a programme of public education with the object of explaining the system of rationing and of giving information as to how the available foods may best be used. In this educational effort the Board of Education, the local authorities and the medical profession have played an important part. Indeed there is nothing more praiseworthy than the efforts that have been made to secure the provision of a midday meal and of milk at school for the largest possible number of children. When the difficulties of premises, equipment and staff are taken into account, the fact that on five days a week some three quarters of a million school-children sit down to dinner together and more than three and a half million are given milk in school must be regarded as a real achievement. The various schemes for the provision of communal meals are contributing in no small measure to the maintenance of a reasonable standard of national nutrition as are the special priorities, in respect of milk and other foods, granted to mothers, young children and invalids. Surveys of groups of the population are being conducted in various parts of the country and for some of these the new Institute of Social Medicine at Oxford will act as a centre where results can be analysed and new methods tested. In this work I have to acknowledge the great help given by the Rockefeller Foundation who have generously provided staff, money and equipment which have made possible this scheme for measuring the effect on the health of our people of the necessary war-time restrictions in diet. At last, then, we have obtained, as a result of the necessities of war, what has been lacking in the past—a real nutritional policy which includes collaboration between the central government departments concerned, a programme of public education and a system of checking results by means of local surveys. Surely these gains in time of war will not be lost in times of peace.

The war has given a new impetus to all forms of health education and the ordinary citizen has responded well to the needs of the times as expressed in the slogan—and these are the days of slogans—"Help to keep the nation fighting fit." The public are more ready than in peace-time not only to listen to simple and often repeated advice, but even to act on it. This quickening of popular interest is reflected in, and stimulated by, the increased publicity which the press, the BBC and the cinema are giving to information regarding health. More than ever before health, in contradistinction to disease, is news, and prevention is acquiring some of the drama of cure. It has therefore been made easier for both central and local authorities considerably to extend their efforts to supplement the educational work carried out so effectively and so unostentatiously in the past by private practitioners, medical officers of health and, above all, by health visitors.

We have enjoyed for over a century the benefits of a Registrar-General's office with a national system for the collection and publication of vital statistics. Causes of death have been readily ascertainable, not so, however, causes of morbidity. An attempt is now being made, through the agency of the Emergency Hospital Service to obtain returns from hospitals of causes of morbidity compiled in accordance with an approved classification. If hospital staffs cooperate willingly in this effort, and there is no reason to anticipate otherwise, we shall have at least means of determining not only the conditions from which hospital patients die but also the conditions from which they recover. Such information is essential not only to the planning of an adequate hospital system but also to the proper understanding of many of our communal medical problems.

THE FUTURE

These then are some of the lessons we are learning in the stress of war. Shall we remember them when peace comes? There are signs that we shall. First of all we have the following statement of the Government's postwar hospital policy made by the Minister of Health in the House of Commons on Oct. 9, 1941:

> "It is the objective of the Government as soon as may be after the war to ensure that by means of a comprehensive hospital service appropriate treatment shall be readily available to every person in need of it. It is accordingly proposed to lay on the major local authorities the duty of securing, in close cooperation with the voluntary agencies engaged in the same field, the provision of such a service by placing on a more regular footing the partnership between the local authorities and voluntary hospitals on which the present hospital services depend. The Government recognise that to achieve the best results and to avoid a wasteful multiplication of accommodation and equipment it will be necessary to design such a service by reference to areas substantially larger than those of individual local authorities. It will be the aim of the Government also to avoid overlapping and uneconomical expenditure by securing the provision of the more highly specialised services at teaching hospitals and other centres selected to serve these wider areas, and by arranging for a proper division of function between hospitals in these areas.
>
> With regard to the financial aspects of the Government's proposals, it is their intention to maintain the principle that in general patients should be called on to make a reasonable payment towards the cost whether through contributory schemes or otherwise. In so far as any new burden may be thrown upon local authorities in providing or maintaining hospital accommodation, or in contributing towards the expenditure of voluntary hospitals, a financial contribution, the extent of which will be a matter for further consideration, will be made available from the Exchequer. Special arrangements for dealing with the teaching hospitals by way of increased educational grants are in contemplation."

Surveys of hospitals are already being conducted in the London area and in the north-west of England; others are about to start with the active cooperation of the Nuffield Provincial Hospitals Trust. These surveys are in the main fact-finding, but their findings should determine in no small measure the pattern of hospital coordination over a given area. The quality of service rendered by hospitals depends almost entirely on the training, skill and experience of those who staff them and it is gratifying to know that this college, with its two sister colleges, has assumed the responsibility of laying down criteria for the training and status of future consultants. A list of consultants is in course of preparation and it is hoped that the colleges will advise as to how these consultants should be distributed throughout the country so that their services may be readily available both to the public and to the general body of the profession. This is no easy task but it is one the colleges are peculiarly fitted to perform.

An interdepartmental committee has been appointed to report on the organisation of our medical schools and on the facilities available for clinical teaching and research. If educational grants are to be made to teaching hospitals the Government must be satisfied that they are so staffed, equipped and administered that those who are privileged to pass through their laboratories, lecture-rooms and hospital departments will receive the best training and experience this country can offer. Nothing less will suffice if the profession is to give the service to which our people are entitled. This college has always rightly regarded medical education as one of its main concerns and it is a hopeful sign that the President has appointed one committee to study the medical curriculum and another to advise on the scope of social medicine and the manner in which the subject may best be presented in our medical schools In this connexion I should like to pay a tribute to the forward policy of the University of Oxford in establishing a Chair of Social Medicine and in particular to the wisdom the Nuffield Provincial Hospitals Trust has shown by its generous support of the university in this venture The Institute of Social Medicine which the Trust has brought into being will, I feel sure, give reality to what has so far been little more than a dream in the minds of some of us and will act as a profound stimulus to other educational centres The great interest which Lord Nuffield has shown during recent years in medical education and research is one of the most heartening signs of our time In the past it has been the hospitals of the country that have in the main benefited by the generosity of public-spirited citizens Too few gifts have come the way of our centres of medical education and research In this we compare unfavourably with North America where private benefaction has time and again enabled work to be undertaken and experiments in education planned that would have been impossible without such aid Indeed, American generosity has not been confined to the North American continent, we owe much to it in this country May I quote only one example out of many After the war of 1914–1918 the whole subject of postgraduate medical education in London was reviewed by a committee of which the Earl of Athlone was chairman This committee recommended that two schools of postgraduate study should be established, one devoted to clinical work and the other to preventive medicine The fact that the London School of Hygiene and Tropical Medicine opened its doors as early as 1929 was entirely due to the provision by the Rockefeller Foundation of the whole of the sum required for site, building and equipment It is unlikely that the opportunity for private benefaction will wholly disappear as a result of this war and I may be permitted to express the hope that some part at least of the moneys so made available will be directed towards the training of those who have the physical, and in large part the mental, well-being of the people in their special charge

Side by side with advances in medical education I hope to see improvement in the training and conditions of service of the nursing profession As earnest of its own goodwill in this connexion the Ministry of Health has set up within its own establishment a nursing section in which nurses are given status comparable with that of medical and administrative officers In future, therefore, all matters concerning institutional or domiciliary nursing will be reviewed in the central government department by members of the profession itself

Another sign of great significance has been the formation by the British Medical Association of its Planning Commission, and, still more, the character of its Interim Report Surely we are entitled to read into this report a realisation on the part of the medical profession that their continued existence as a series of isolated units is in the interests neither of themselves nor of the public they serve, that if private practitioners are to take their proper place in the conduct of public medical services the medical profession will have to submit to some agreed measure of reorganisation, and that the better “ utilisation of medicine by the State,” to which the distinguished first medical officer in central government so eloquently referred, must form an essential element of any post-war policy of social reconstruction

These three proposals for a coordination of hospitals, for the better organisation of the medical profession and for what we hope will be a simplification of the medical curriculum, coupled with greater emphasis on the social aspects of medical practice, are all inter-related They are the intimate concern of all branches of the profession and they can be given effect to only with the help and goodwill of the profession

---

Bacot Lecture —The first Bacot memorial lecture of the Lister Institute of Preventive Medicine will be given by Prof P A Buxton, at the London School of Hygiene, Keppel Street, W C 1, on Friday, Oct 30, at 3 PM He will speak on Bacot’s work on the louse and some of its recent developments

---

TRYPANOSOMIASIS TREATED WITH ‘PENTAMIDINE’

T L Lawson, M B LPOOL, D T M & H

This paper records the treatment of a series of 53 cases of Gambian trypanosomiasis with 4 4 diaminodiphenoxypentone (‘ Pentamidine ’ or M&B 800) Altogether 57 cases were treated, but 4 of these were not re-examined after a lapse of time since conclusion of treatment, hence I have omitted them The cases were not selected, but are the first 53 diagnosed in the West Nile district of Uganda in 1941 This work has been carried out under slightly difficult conditions, in a primitive part of the world Most of the cases dealt with probably had not been infected for longer than 3–4 months at the most, since the entire population is examined for sleeping sickness once every 3 months

On arrival of a case after the history had been taken, clinical examination was carried out Often patients gave no history of any illness, sometimes their account was genuine but sometimes they feared possible consequences if they admitted any complaint Headache, pains all over the body, “ not feeling well,” tiredness and sleeping during the day were the commonest symptoms Enlarged cervical glands was the most usual sign encountered, often these glands were hard, not soft as is usually stated, more rarely the face was puffy Fever I never found, rises of temperature from other causes are so common with Africans that one would not get a reliable history of fever due to sleeping sickness Rashes were never seen As about 90% of the population have an enlarged spleen that sign is no help in diagnosis In advanced cases in adults tremors of the tongue, a Parkinson-like rigidity and more rarely a cheerful garrulous madness were the most usual signs In similar cases in children choreiform movements were common More rarely one saw, in all ages, the onset of true sleepiness in which a patient will just go to sleep on a stool or any odd place Absence of knee-jerks is a late phenomenon and Kerandel’s sign was never elicited

After clinical examination the enlarged cervical glands were punctured, the juice being examined under the ⅙ in lens for living trypanosomes The following examinations were also performed red and white blood-cell count, estimation of hæmoglobin and colour-index, differential white-cell count, and “ separation of the blood ” test Lumbar puncture was carried out, and a cell count was done on the cerebrospinal fluid We were unable under the conditions prevailing to perform accurate protein estimations on the CSF Instead we used the simple Nonne-Apelt reaction with saturated ammonium sulphate for testing for excess of globulin Lastly the CSF was centrifuged and the deposit examined for trypanosomes after staining with Leishman stain A thin film of the blood was also examined for trypanosomes Out of 49 cases with positive gland puncture only 2 had trypanosomes in the thin film In some cases the sedimentation-rate was estimated to see if it served as a guide to the degree and rate of cure

At the outset we experimented with auto-agglutination of the blood in the hopes that it would serve in the same manner as a sedimentation-rate, but we found it totally unreliable

In the first 20 cases we carried out the ordinary triple centrifuge method of looking for trypanosomes in the blood In all of these trypanosomes had been found in the glands, but in only 2 was the test positive With the method of separation of the blood, trypanosomes were found in 7 cases out of 33 which had the parasite in the gland juice

For this test 8 c cm of blood is taken and diluted with 2 c cm of 3 8% sodium citrate (these proportions were chosen because a portion of the same blood serves for the sedimentation rate) The mixture is left standing for 2 hours in a narrow test-tube The plasma just above the level of the top of the sedimented cells is taken off, a film of the plasma made and stained with Leishman stain

TREATMENT

Pentamidine was started after all tests were complete, the drug being given intravenously daily Every day gland puncture was performed until the gland juice was negative for at least 2 consecutive days After the third injection all the investigations mentioned above were repeated except the sedimentation-rate After the tenth injection, which completed the course for most of the patients treated, the investigations were again repeated Also if a patient had a second course, the process was repeated once more at the conclusion. Finally all the cases were re-examined 2–3 months after the end of treatment

Facilities for weighing the patients not being available the dosage was regulated in rather a rough manner according to age Patients between 6 years (our youngest patient) and 10 were given 0 05 g at each injection Patients of 11 and over were given 0 1 g at each injection Of the 53 patients in the series 13 had 10 injections (a total of 0 5 g for those under 10, and 1 g for those over 10), 6 patients had 20 injections (1 and 2 g for the two age-groups), one man of larger build than average had 10 injections of 0 1 g followed by 10 of 0 2 g (a total of 3 g), one woman with a heavy infection had 3 injections of 0 1 g followed by 5 of 0 2 g, but she was so weak after this that she was unable to get out of bed, 2 patients had 6 injections, one getting a total of 0 3 g and the other 0 6 g In one patient (one of the 4 not followed up) the dose was gradually increased at each injection, after 0 2 g he was not uncomfortable, so the dose was increased to 0 5 g, after this he collapsed suddenly and was almost pulseless for about ¼ hour, after which he recovered with nothing worse than a headache

All the injections were given intravenously daily, pentamidine being dissolved in sterile distilled water The drug is said to be soluble to the extent of 40 mg in 1 c cm of water at 37° C Our experience has not confirmed this At the outset we dissolved 100 mg in 5 c cm of water, but this took such a long time that we increased the water to 10 c cm, so that the strength was 10 mg per c cm of water In no case was there any evidence of perivenous inflammation Since it is unlikely that about 600 intravenous injections (some to children) were given perfectly, the drug cannot have any seriously harmful effect on the subcutaneous tissues

CLASSIFICATION AND RESULTS

It is impossible to classify reliably cases of sleeping sickness on clinical manifestations alone Hence each factor has been taken separately and the total effect summed up

On examination 2–3 months after the end of treatment, 41 patients were clinically cured, 3 much improved, 4 improved and 4 unaltered or worse One had died Thus on purely clinical assessment only 5 out of 53 were totally unaffected by pentamidine Judged by gland puncture, 4 cases were negative before, during and after treatment Of the remaining 49 in the series, negative results to gland puncture were found after the first injection in 31, after the second injection in 12, after the third injection in 5 and after the fourth injection in one All the cases, once they became negative to gland puncture remained so At later examinations they were all either still negative or had no palpable glands Hence as regards gland puncture 100% cure could be claimed

Triple centrifugalisation and separation of the blood yielded 9 positives, trypanosomes were also present in 2 thin blood-films in this group After 3 injections (the test was not done every day) all of these were negative and never became positive again

On results of examination of the CSF, cases were classified as follows

Group	Cells per c.mm CSF	Cases in group	Cases with excess glob	Cases with trypanosomes +
1	Under 10	8	0	0
2	10–80	22	3	0
3	80–200	7	3	2
4	Over 200	16	16	5

The 2 cases with trypanosomes present in group 3 showed an unexplained rise of cells, after the third injection, to over 200 per c mm In all 7 cases with trypanosomes the organisms disappeared during treatment, after 3 injections in 4 cases, after 10 injections in 2 cases and after 20 injections in 1 case One case relapsed after 2 months, trypanosomes being again found in the CSF, this was the only case out of the 53 in which trypanosomes were found in any situation on re-examination

As may be imagined, treatment had no significant effect on the CSF cell-count of cases in group 1 Of the cases in group 2, 10 out of 22 showed a reduction in cell-count while under treatment One case refused further lumbar punctures, and one case was not lumbar punctured (owing to advanced pregnancy) until she was re-examined, when she had 3 cells per c mm only In one case there was no alteration during treatment Some rise of cells above the figure at the end of treatment was found in 7 of these cases at re-examination, but this was not great In group 3, 5 cases out of 7 showed a reduction of CSF cells during treatment The other 2 cases actually showed an increase in cells during this period These 2 cases both had trypanosomes present in the CSF When they were re-examined 4 cases out of the 7 showed an increase of cells over and above the original count In group 4, 11 cases out of 16 showed a reduced count on the completion of treatment In one the count was unaltered and in the other repeated attempts at lumbar puncture failed On re-examination 5 showed a slight increase in the cell-count and 5 an increase over and above the original count One case in this group died after the course of treatment was completed

It is interesting to note that in 12 cases the clinical findings and the results of CSF examination disagreed Of the cases treated, 3 had relapsed after having been treated with 'Antrypol' (BDH) and tryparsamide 2 years ago They had received 3 injections of 1 g of antrypol and 7 injections of 3 g of tryparsamide Of these cases, 2 showed no improvement except that the CSF was cleared of trypanosomes in one The third case improved remarkably in all respects

Case 1—A man of 23 with no complaints and no signs except enlarged cervical glands On March 4, 1941, gland puncture positive Urine, no albumin CSF, no trypanosomes or excess globulin, cells 5 per c mm Triple centrifuge method no trypanosomes On March 6, given pentamidine, 0 1 g Dose repeated next day, gland puncture positive. March 7, dose repeated, gland puncture negative "Separation of blood" test no trypanosomes CSF no trypanosomes or excess globulin, cells 6 per c mm From March 11 to 17 he received 0 1 g pentamidine daily March 18, clinically well, gland puncture negative Separation of blood no trypanosomes CSF no trypanosomes or excess of globulin, cells 8 per c mm Urine, no albumin March 19, clinically well No palpable glands Separation of blood no trypanosomes CSF no trypanosomes or excess of globulin, cells 9 per c mm Blood counts during the illness were as follows

CASE 4—A girl of 10 years who had had pains all over the body for a month Sleeping much during the day, severe headaches Temperature and pulse normal Seemed normal mentally, severe tremor of tongue and fingers, enlarged cervical glands March 27, gland puncture positive Separation of blood, negative CSF trypanosomes present, excess globulin, cells 990 per c mm Urine no albumin throughout Pentamidine 0 5 g given on March 29, and again on March 21 and April 1, on both of which days gland puncture was positive April 2, gland puncture negative, separation of blood, negative CSF trypanosomes present, excess globulin, 764 cells per c mm From April 4 to 10 given 0 5 g of pentamidine daily April 19, no pains, tongue still slightly tremulous, gland puncture and separation of blood negative CSF no trypanosomes, excess globulin, cells 690 per c mm June 23, feeling very well No pains or headache Working in fields Not sleeping during day, no palpable glands, no tremors Separation of blood, negative Blood counts during treatment were as follows

Date		Red cells	Hb (%)	White cells per c mm	Differential count (%)				
					P	L	M	E	T
March	27	2,544,000	80	7800	55	30	7	7	1
April	2	2,920,000	80	6600	25	56	9	6	4
,,	4	3,496,000	80	8200	35	57	2	6	0
June	23	3 822,000	90	6800	40	40	15	5	0

In this series of cases there are two complete failures the case which died, and case 2, recorded above Added to these are 11 of the more advanced cases which—though not complete failures or relapses—cannot be claimed to the credit balance of the drug A double dose was given to 6 cases (i e, a total of 1 g to those under 10 and 2 g to those over 10) In all of these cases the CSF contained over 200 cells per c mm, and trypanosomes were present in the CSF of 3 All showed a reduction of cell-count and disappearance of trypanosomes while under treatment On re-examination 4 had more cells per c mm of CSF than at the original count, of these, 2 were clinically unchanged, 1 improved and 1 clinically cured Of the other 2, there was a slight increase in cells in 1, and in the other the cell-count remained low, both appeared clinically well One case had a treble dose (3 2 g in all), trypanosomes disappeared from his CSF, and his cell-count fell under treatment, but on re-examination it was found to be higher than it had been originally Clinically he was much improved Of 2 patients who had just over half the regular dose 1, an adult, was clinically cured, but as she refused a second lumbar puncture the effect on her CSF was unknown (she had 73 cells per c mm in the original count) The other, a child, was much improved clinically, her CSF cell-count was 560 per c mm before treatment, 280 at the end of treatment and 380 on re-examination

The sedimentation-rate was done in 7 cases, using the Westergren technique, before and after treatment and on re-examination In the table the rate at the end of treatment is omitted because in all cases it was almost identical with that before treatment was begun Figures at the end of 1 hour only are given

SEDIMENTATION-RATES BEFORE AND AFTER TREATMENT IN 7 CASES

Case	Before	After	Clinical result	Pathological result
5	140	90	Cured	Cured
6	113	78	,,	,,
7	125	50	Impr	Impr
8	118	141	Cured	Cured
9	46	55	Not impr	Some impr
10	110	100	Cured	Impr
11	40	7	,,	Cured

All the rates are very high, a high proportion of the patients had malaria and worm infestation as well as sleeping sickness, and it is not easy to say how far the high rates were due to concurrent infection Since in two cases (8 and 10) the results do not correlate well with the clinical and microscopic findings, I do not think that much reliance can be placed on this test

TOXIC EFFECTS

In 36 cases (67 9%) some immediate toxic manifestation followed injection of the drug In order of frequency these were increased pulse-rate, the rate sometimes being almost doubled (often the only sign), feeling of heat all over the body, preceded by a feeling of the drug passing all over the body, itching followed by an almost uncontrollable scratching, especially of the genitalia, nausea and vomiting, giddiness, shivering We were able greatly to reduce the tendency to nausea and vomiting by making the patients take copious draughts of cold water while the drug was being given In a few cases a slight fall of systolic blood-pressure was recorded One case, given 0 5 g of the drug at one injection had a complete collapse resembling surgical shock He was almost pulseless for about a quarter of an hour, but recovered rapidly All the symptoms mentioned above lasted a few minutes only, and were less severe after successive injections In one woman, however, the effect was cumulative, after five injections of 0 2 g she became so weak that she was unable to get out of bed, she regained her strength in two days when the drug was stopped Another woman who was 7½ months pregnant was given a full course (10 injections of 0 1 g) with no undesirable results, she gave birth to a healthy child six weeks later A few patients, several minutes after the injection, developed headache, aching in the bones and colicky abdominal pains No jaundice or other signs of liver disturbance were seen Five cases had a trace of albumin in the urine at the end of treatment, *no casts were present* Of these, 1 had albumin in the urine before treatment was begun Actually, 6 other cases had albumin in their urine before treatment was started, in 5 of these it cleared up before the end of treatment The possibility of any renal damage is obviously low

There was little change in the red-cell count or hæmoglobin, in a few cases there was some decrease of the anæmia which was common to most cases In 9 cases leucopenia developed, the most serious showing a white-cell count of 7600 cells per c mm before and 3200 after treatment In 15 cases there was leucocytosis, the maximum figures being 5200 white cells per c mm before and 14,800 after treatment In 28 cases (52 8%) there was a tendency to relative agranulocytosis, in 7 cases this was partly or completely compensated for by a generalised leucocytosis

Typical figures in different cases were as follows

	Polymorphs (%)				
Before treatment	70	62	49	33	50
After ,,	45	31	31	20	29

In 9 cases there was leucopenia of agranulocytic type, in 1 case the polymorphs fell to 650 per c mm On re-examination the differential white-cell count had returned to normal in all except 8 cases in these some slight reduction of polymorphs was still evident A double course of the drug increased the tendency to agranulocytosis, but at most by 10%

CONCLUSIONS

The following facts are to the credit of pentamidine It produces a rapid peripheral sterilisation of the blood and gland juice

Treatment is complete in 10 days instead of 10 weeks, as with other drugs available, this is extremely important, from the point of view of the patient and for the preventive medical aspect

Toxicity is low, especially in comparison with tryparsamide (which is responsible for many cases of blindness in Africa) The effective dose is not more than half the toxic dose and probably almost a fifth the lethal dose

On the debit side are its lack of success when the examination of the CSF shows serious CNS involvement When the cell-count in the CSF is above 80 per c mm, it is probably safer to use one of the pentavalent arsenicals Some cases with counts above that figure were cured, but others were not

It is not safe to base too much reliance on the analysis of a mere 53 cases, but it does seem that this is probably the best drug so far produced for the early cases of sleeping sickness If it is used, however, lumbar puncture should be done in all cases, and no case with a CSF cell count of 80 per c mm or more should be given pentamidine unless it can be carefully followed up Control differential white-cell counts during treatment are advisable but not absolutely essential if dosage is reasonable It is not practicable to give exact dosage per lb of body-weight of the patient, since in Africa treatment is often in the hands of people who cannot calculate such niceties Our rough method probably suffices in all but the most civilised surroundings

I wish to thank Mr P Muganwa, my assistant medical officer, and Mr J Muwanga, my laboratory orderly, for their help, and the Hon Director of Medical Services of Uganda for permission to publish this paper

FEBRILE REACTIONS AMONG SMALLPOX CONTACTS

WILLIAM NAPIER
M D GLASG
PHYSICIAN SUPERINTENDENT

ALICE M INSH
M B GLASG, D P H
RESIDENT MEDICAL OFFICER

SHIELDHALL FEVER HOSPITAL, GLASGOW

THE outbreak of variola major in Glasgow, and the conversion of this hospital for the time being into a reception house for contacts, gave us the opportunity to observe febrile reactions among these persons and compare them with those recorded by other observers Between June 27 and 30, 1942, 92 contacts were received —22 men, 28 women and 42 children under fourteen years, 50 had had close association with a smallpox patient over periods of three to eight days, 27 had less intimate exposure but lived in the same house as a patient, in 15 contact was limited to one or two occasions only All contacts were vaccinated on the day of admission to the reception house, with success in 43, 29 who showed little or no response after several days were revaccinated successfully, while 20 proved insusceptible to the vaccinia virus It was often noticed that a second attempt at vaccination appeared to activate the earlier insertion which till then had shown no sign of activity In contrast to more normal times, there were no objectors, conscientious or otherwise, to vaccination

No fewer than 40 contacts showed febrile reactions during the period of quarantine, of which 30 were clearly due to vaccinia and 2 to variola, while 8 formed an observation group that presented some difficulty in diagnosis All other contacts remained well except a child of one year who developed a mild chickenpox without rise of temperature and—an unusual event—infected a nurse with this disease in a severe form

Vaccinia —The onset of pyrexia varied between the 6th and 13th day after vaccination, in 11 cases being on the 10th day Its duration was from one to three days, save in four instances where it was prolonged to the 4th or 5th day In five the temperature reached 101° F or over Vaccinia was the obvious cause of these reactions, the local lesion being sometimes very severe with much œdema of the arm and painful swelling of the axillary glands Women tended to react more acutely than men and children, for a number of them had never been vaccinated before No example of generalised vaccinia or other eruption was observed

Variola —Smallpox appeared in 2 contacts, as follows

CASE 1 —Girl, aged 14 yr, infected from her father who had been ill for 7 days before removal to hospital Child vaccinated in infancy and again successfully on admission to reception house on June 29 On July 6 her temperature rose to 100 8° F with no symptom other than headache On July 8 it fell to 99 6° F, and four macules were seen on cheek (2), wrist and leg By the morning of July 9 the face spots already showed vesiculation, while the others were hard papules The child was notified and removed, her mother (also a contact) protesting bitterly that these heat spots were quite unlike her husband's eruption Such a mild infection in a person not under observation might easily have escaped detection

CASE 2 —Girl aged 20 yr A close associate of her sister who had been ill for five days and was regarded at first as a case of chickenpox She was admitted on June 30 and successfully vaccinated, no previous vaccination On July 8 her temperature rose rapidly to 101 4° F and the classical symptoms of shivering, headache, backache and vomiting were present On July 10, when her temperature reached 104 6° F after a severe rigor, her forehead was covered with a fine papular rash and three papules were seen on the right forearm and one on the left palm She was notified and removed When seen by us four days later in the smallpox hospital, she had a dense confluent eruption with no evidence of modification by vaccination She died on the 15th day of eruption

Observation group —The following 8 contacts with febrile reaction presented doubtful features and were isolated on suspicion of variola

CASE 3 —Woman, aged 28 yr, had 2 days' fever beginning on the 10th day of quarantine, with maximum 102° F Vaccination + Complained of headache Evidence of acne to which she is subject On the 12th day a few fresh macules appeared on brow and shoulders, they remained for some days without developing

CASE 4 —Girl, aged 3 yr, had 2 days' fever, beginning on the 10th day of quarantine, with maximum 99 8° F Vaccination + On the 12th day four discrete papules appeared on her hand, leg and abdomen (2), which lasted only 24 hours and showed no development

CASE 5 —Boy, aged 4 yr, had 2 days' fever beginning on the 7th day of quarantine, with maximum 100 8° F Vaccination + No complaint Two transient macules on face and thigh several days later

CASE 6 —Boy, aged 13 yr, had 6 days' fever beginning on the 7th day, maximum 101 2° F Vaccination + +, with swollen, tender axillary glands No other complaint One macule on cheek noted on 1st day of fever, it soon faded

CASE 7 —Boy, aged 2 yr, had 6 days' fever beginning on the 8th day, maximum 102° F Vaccination + Has scabies On the 12th day fresh papules were seen on trunk (6), arm (2), face (1), they showed no development

CASE 8 —Woman, aged 27 yr, had 5 days' fever beginning on the 9th day, maximum 100 4° F Vaccination, slight reaction No complaint Has scabies Papules appeared on the 12th day on brow (2), trunk (3) and forearm (1) Next day those on brow and forearm were hard and papular, all gradually subsided without vesiculation

CASE 9 —Man, aged 42 yr, had 2 days' fever from 12th day, maximum 102° F Vaccination, slight reaction Headache and shivering On the 14th day a few spots appeared on forehead which lasted for two or three days, becoming hard and papular, but showed no further development

CASE 10 —Boy aged 17 yr, had 6 days' fever from 8th day, maximum 101 4° F Vaccinated on the 3rd day of exposure but without effect till a second vaccination on the 7th day activated the first insertion The local reaction was not enough to account for the degree of fever His temperature rose sharply to a maximum of 101 4° F and remained fairly high for five days He was pale, tired looking and drowsy but made no complaint at any time Chest, abdomen and urine were negative On the 3rd day of fever, 3 spots were observed on the soft palate closely resembling the lesions of chickenpox in that situation They had the appearance of ruptured vesicles A few hours later they were less evident, and next day when we expected to find a smallpox exanthem there was no trace of them or of eruption Three macules made their appearance on the face on the 5th day, however, when the temperature was falling On the 6th day one of them was hard and papular and two fresh macules were seen over the scapula and on the forearm By the 7th day the boy's temperature was normal and the spots had disappeared without trace

DISCUSSION

The difficulty of deciding what importance to attach to a few scattered spots is not reduced when the subject already suffers from acne or scabies In three patients the new lesions observed might well have been due to one of these diseases On the other hand, the tendency of the spots to appear on the second or third day of fever is noteworthy We formed the opinion that the eruption in cases 3–7 was not variolar and that the fever was attributable to vaccinia Patients 8 and 9 had been vaccinated on the 5th and 7th day respectively of exposure to smallpox, but the general reaction as indicated by the temperature chart seemed out of proportion to the local lesion on the arm Both had macules on the brow which developed into hard papules , one had headache and shivering Case 10 showed very suggestive lesions on the palate Could these cases possibly be examples of smallpox very much modified ? We were inclined at first to think so , but since similar rashes and symptoms were occurring in the city after vaccination it became apparent that the diagnosis of modified smallpox could not be upheld, and the patients were not notified or removed to the smallpox hospital

Chalke[1] describes maculopapular eruptions following vaccination, but does not associate them with any rise of temperature He mentions that such rashes are often accompanied by urticarial or erythematous patches and regards them as akin to serum rashes None of the doubtful eruptions observed by us appeared to come within this category Conybeare[2] describes febrile illness in 7 of 16 contacts of a case of variola Each patient had headache, shivering and muscle or joint pains, with fever lasting 2–7 days and maximum 101°–103° F From his description, one was clearly a case of modified smallpox None of the others had a suggestive rash All but one had been revaccinated, and their illness may have been due to vaccinia But it is significant that the unvaccinated contact suffered from the same group of symptoms, so that the possibility of variola cannot be ignored Bowe[3] recently described three examples of febrile illness among contacts None had an eruption, but headache and backache were prominent in two Temperatures rose to 101° F and fever lasted for 1–4 days No revaccinations had been done and Bowe seems justified in regarding them as possible cases of modified smallpox

The conclusions we have arrived at by the study of these groups of cases are these (1) Smallpox may be by no means easy to recognise even in known contacts under constant observation (2) Careful discrimination is required to decide whether febrile attacks in contacts are due to vaccinia or variola (3) In a newly vaccinated person vaccinia is by far the likeliest cause of fever with a sparse eruption, but even a few spots showing the typical development, as in case 1, may be sufficient to indicate variola with certainty (4) When vaccinia can be ruled out, a short febrile illness, with or without transient spots, occurring in the second week after exposure offers presumptive evidence of variola

SUMMARY

Febrile reactions in 40 smallpox contacts were found to be due to vaccinia in 30 cases and to variola in 2 The remaining 8 were less easy to classify, but all were finally relegated to the vaccinia group

TOXIC BLOOD-LEVEL OF SULPHANILAMIDE FROM LOCAL APPLICATION

R A GORDON, M D TORONTO, B SC SASKATCHEWAN, D A
MAJOR RCAMC

V H BOWERS
M B, B SC LOND

PLASTIC SURGERY TEAM, RCAMC

THE following case seems worth recording in view of the high level of free sulphanilamide reached in the blood after local application to burned areas.

The patient was admitted to hospital four hours after he had been burned by an explosion of petrol He was suffering from burns involving the whole of the right hand and arm, part of the left hand, left arm, face and neck, about half of the back of the chest, and part of the front of the chest and dorsum of the penis It was estimated that 22% of the surface area of the body was burned The burns appeared to be cutaneous only, and were called second degree There was no œdema

On admission the burned areas were covered with dry gauze bandages These were removed by wetting with saline, the burned areas were gently cleaned with soap and water, and the fragments of dead skin were cut away The areas were then covered with a film of sulphanilamide powder from an insufflator, and dressed with tulle-gras, moist saline gauze and cotton-wool This was repeated on the day after admission and again on the second day Blood chemistry, hæmatology, clinical course and treatment are outlined in the table Throughout this period there was no disturbance of the fluid balance, and although the blood free sulphanilamide rose to 59 mg per 100 c cm the blood-urea remained at 31 mg per 100 c cm throughout The clinical signs of toxicity were cyanosis and drowsiness with mental confusion The patient recovered completely

TABLE SHOWING BLOOD CHEMISTRY, HÆMATOLOGY, CLINICAL COURSE AND TREATMENT

Date in July	Hb %*	Red cells (millions per c mm)	White cells (per c mm)	Plasma proteins %	Plasma chloride	Blood urea	Blood sulphanilamide (free)	Clinical state and treatment
					(mg per 100 c cm)			
7th	100	4 8	14,000	5 5	590	35		Admission Dressed with sulphanilamide at 11 PM and again at 11 AM on July 8
9th (11 AM) (5 PM)	107	5 5	19,600	4 5	610	31	29 59	Cyanosed , dressed with sulphanilamide Cyanosed , drowsy , confused , BP 130/90 , resp 28 At 5 15 PM 1000 c cm 5% glucose in normal saline given intravenously , oxygen by nasal catheter
10th	86	5 4	22,800	5 5	610	31	30	Cyanosed , drowsy , rational
11th	92	4·7	27,500			31	24	Slightly cyanosed oxygen discontinued 24 hour specimen of urine volume 1150 c cm containing 14 g free sulphanilamide , deposit of crystals of acetyl sulphanilamide only , no albumen
13th	89		22,300	5 0	575		15 5	Seemed well
14th							Less than 1	Recovered

* Sahli s (acid hæmatin) method , 14 5 g per 100 c cm taken as 100

PERFORATED PEPTIC ULCER
IN WAR-TIME

IAN D. RILEY, M.D., B.SC. LEEDS, M.R.C.P.
FORMERLY RESIDENT MEDICAL OFFICER AT THE ROYAL VICTORIA INFIRMARY, NEWCASTLE ON TYNE

IN the Royal Victoria Infirmary there were 200 ulcer perforations in 1939, 222 in 1940, and 251 in 1941. This rise coincided with a small fall in the total number of surgical admissions. Figures for 1926, the year of the general strike showed no comparable rise. During periods in which air-raids were frequent in London, Bristol and Liverpool an increase occurred by a third to six times the usual number of cases,[1] whereas during months without air-raids the figures were normal. Air raids had a less obvious effect in Newcastle than in these other cities, probably because the bombing was less severe. The average number of perforations during months in which raids took place was 19, compared with a monthly average throughout the whole of 7 years of 17. The number of perforations in January was always consistently high, the average being 26. The totals for the Royal Infirmary were as follows:

Year	*Perforations*	*Total surgical admissions*	*Average age*
1926	186	7192	40
1931	156	6931	42
1937	181	6862	42
1938	198	6909	44.1
1939	200	6785	41.4
1940	222	6418	42.5
1941	251	6181	42.2

The cause of this progressive increase is not easy to determine. There has been a change in the last 40 years, both in the site of the lesion and in the type of patient whose ulcer perforates.[2] In 1900 young women frequently suffered from perforations on the lesser curvature, whereas during the last 20 years perforation of ulcers in the pyloric region in men aged about 40 years has been common and young women have rarely been affected. In the Newcastle series the average age was 42 years. This suggests that the increase is not due to those factors which caused perforations in young women 40 years ago.

Other factors which aggravate ulcers are worry, bad dietary habits and overwork. Real anxieties, not trivial cares, aggravate the symptoms and some grave domestic crisis often precedes perforation.[3] The young are more liable to be disturbed by uncertainties of employment than the middle-aged, who are chiefly concerned with social position and financial security. Uncertainty of employment is increased during war-time.[4]

Four cases of adult scurvy were present in Newcastle wards in July, 1942. Since perforations increased tenfold during famine in Russia[5] this may mean that malnutrition is also a factor in the present increase. The conditions under which food is served and eaten are more important than its nutritive value. Long hours of work with hasty sandwich meals, at irregular intervals, were the cause of much gastric disorder in London Transport workers, as shown by the Royal Commission's report on the causes of the 1937 strike.[6]

Despite statements that the health of the nation is better than it has ever been before, there is evidence that digestive disorders and perforation of peptic ulcers have become more common. Perhaps shorter hours of work and improved canteen facilities would result in less time being lost on this account.

I wish to thank the hospital registrar for the figures, and Dr. C. J. Polson for his help.

Reviews of Books

Gray's Anatomy

(28th ed.) Editors: T. B. JOHNSTON, M.D., JAMES WHILLIS, M.D., M.S. Durh., F.R.C.S. London: Longmans Green and Co. Pp. 1558. 60s.

BY all the rules the review of a textbook that has reached its 28th edition should be confined to a short notice of the added merits displayed in its latest appearance. But Gray, long accepted as a—or even *the*—standard textbook of British anatomy, must be regarded as something more than the product of a particular editor and the enterprise of a publisher. When Gray started its career it was distinguished by a series of beautifully clear, accurate and original anatomical drawings. It largely avoided the snare into which so many British textbooks fell of incorporating illustrations of varying degrees of accuracy, in all sorts of styles, culled from any available source. For many years this tradition has been lost, which might be all to the good were accuracy and clarity gained; but one has only to compare the more recent figure 1120 placed in fatal juxtaposition with the older and more accurate figure 1119 (or even with the far older figure 491 of the 12th edition) to appreciate that the attractive colour of the artistic wash drawing cannot condone the placing of the parotid duct on the immediate zygomatic origin of the masseter, nor of the angle of the mandible in the place depicted. When the student wishes to apply the knowledge derived from figure 1120 to the study of the surgical anatomy of the part—as depicted in figures 1280 and 1282—he will encounter confusion. Again, colour cannot be said to be attractive in such figures as 565 (repeated as 630) and 568, nor helpful when overlap or incorrect distribution leads to confusion as in figures 503, 520 and 587. In 557 the synovial membrane is said to be indicated by colour but as a matter of fact, while two bursæ unconnected with the joint are thus distinguished, the synovial membrane of the joint itself remains in part colourless. A figure depicting the disposition of anatomical structures should correctly represent the condition seen in an actual dissection; many of the illustrations recently added to this (and other) British textbooks show little evidence of having been drawn from the actual part. A diagram, on the other hand, represents in simple form a condition assumed to exist, and its value depends on the validity of that assumption. Fig. 1108 still shows the testis descending to the scrotum beneath a peritoneal covering; fig. 604 (unfortunately repeated as fig. 608) represents a state of affairs that has long been known to have no real existence. These should have been deleted long ago, especially since in some cases the text shows more enlightenment, so that a real confusion is created for the student. Thus the development of the upper lip is described more or less in conformity with what is known of its human method of formation; this teaching is illustrated by the obsolete diagrammatic fig. 122, depicting a state of affairs altogether at variance with the description.

Revision of the section dealing with the action of muscles has led to some lack of coordination between the description of joint movements and of the actions of individual muscles. The medial rotating action of the iliopsoas is mentioned on p. 624 but on p. 491, where medial rotation of the hip is dealt with, this muscle is omitted. On p. 604 the brachioradialis is rightly said to act simply as a flexor of the elbow-joint, but on p. 470 pronation and supination are added to its rôle; such instances could be multiplied. But it is a little depressing to find the two sections unanimous in asserting that the extensor communis digitorum acts solely on the metacarpophalangeal joints and has no action on the proximal interphalangeal joints.

Anatomical nomenclature has provided the usual crop of ambiguities. In figure 1142 the veins on the underside of the tongue, which we used to know as the ranine veins, are indicated as "venæ com. n. hypoglossi." In the text two lines above this figure, they are alluded to as the lingual veins: the student takes his choice. It is to be hoped that his examiner does not elect to call them "venæ sublinguales." Perhaps the height of confusion is attained when such terms as "deep transverse muscle of the perineum;" "constrictor urethræ," "compressor urethræ," "external sphincter," "sphincter urethræ" and "urogenital diaphragm" are bandied about The confusion will hardly be dispelled by reference to figs 604 or 608, nor will the text help Of the "sphincter vesicæ," the student learns "its main function is to prevent the regurgitation of semen into the bladder during ejaculation" He may wonder what it is doing in between times, and why it is so well developed in the female but as no mention is made of its existence in the female he will perhaps assume its absence The writer of this section is evidently perplexed because the sphincter vesicæ is "an involuntary muscle," while "the external sphincter or sphincter urethræ is under voluntary control after early infancy"

It would be of little avail to attempt to list even a representative series of errors of omission or commission The hiatus muscularis of the appendix still receives no mention though it was described and figured by a British anatomist more than forty years ago and has long since taken its place in international literature The prostate is still described as "surrounding" the urethra and in every figure, whether frankly diagrammatic or supposedly drawn from the actual part, the anterior aspect of the urethra is depicted as a generous bulge composed entirely of prostatic tissue (figs 605, 1225, 1227, 1300) The student is still instructed that the prostate is "about the size of a chestnut" and that the bulbo-urethral gland "is about the size of a pea" One distinguished anatomist, who objected to the expression "as large as a pea," had no objection to the description "twice the size of a split pea," because he maintained that split peas were more uniform in size than whole peas, but it is high time these things passed from scientific literature The system of giving references to published work in footnotes, instead of providing a proper bibliography, has ever been a tiresome vice of British textbooks The vice is accentuated when the reference is as trivial as are many of those provided in this book

Presumably whatever the content of the curriculum provided for the medical student, there should be a recognised and authoritative British manual of anatomy which presents, in the clearest possible manner, the essential facts of the subject necessary for his guidance in his professional course, and in addition, and for reference only, a real textbook of the subject at least as good as the best produced on the continent of Europe. We have at present no such book and there seems to be little likelihood that the present system of pouring new wine of doubtful virtue into old bottles of undoubted frailty is capable of producing one

Expectant Motherhood

Nicholson J Eastman, MD, professor of obstetrics in Johns Hopkins University London John Murray Pp 174 6s

Pregnancy, says Professor Eastman in his foreword, should be a healthy, happy time, for no other event confers so much in deep-seated, abiding contentment Even that old bogy, the confinement, has at last been laid low and labour may be faced with equanimity and even nonchalance since, as he informs the mother to be (with a command of language that Mr Beverley Nichols might well envy), the doctor "will send you off with a magic pill to some distant country of dreams" The radiant little lady, drawn from the best stratum of New York society, to whom presumably this handy little book is addressed, has much to learn from it She may carry on with her social life, indeed it is brave and wise to do so, labours which start at the bridge table are often the easiest in the long run, smoking, provided a modest ten cigarettes per day is not exceeded, can do little harm, neither can a glass of wine or the occasional cocktail "Friends, movies, novels and even the comic strips are more wholesome diversions than thinking about pregnancy" There is a lot of information about fertilisation and some rather disturbing pictures of the female genital organs and the fœtus in various stages of its development, but the chapters on diet, hygiene of pregnancy and important danger signals embody much useful and sensible information Every page has a little tip—e g, "If your waters should break when you are downtown it is judicious to get a taxi and go direct to the hospital Your husband can bring your grip later."

British Rebels and Reformers

Harry Roberts London William Collins Pp 48 4s 6d

Dr Roberts is of course at home among the rebels—with Lord Shaftesbury, Thomas More, John Wycliffe, Hugh Latimer, John Ball, Robert Owen, William Lovett, Bernard Shaw and bold William Cobbett and all We have had in our day some formidable champions of the rights of the ordinary man, and in reading this book it is strange to find how often they fought not for new reforms but to get old rights back—"to recover" as Thomas Attwood put it in 1830 (after a good dinner) "the ancient liberties of our country" It seems as though freedom is something which can only be kept by constant vigilance—as though man must always watch for the inroads which self-interest, that natural component of his nature, can make into the interests of the whole group Against this force, as Dr Roberts shows, has been set again and again the resistance of those who "are moved to protest against injustice and tyranny of which they themselves are not victims" These rebels look out at us from cleverly chosen pictures (the palm goes to the one of Sydney and Beatrice Webb) And from John Ball leading the peasants' revolt to Elizabeth Fry cleansing the prisons they were moved by this honest indignation In his last two paragraphs Dr Roberts begins another and much longer book, for he turns to the future and remarks provocatively "A democratic industrial system in which the majority of the people are little interested is not worth contemplating" Much of our welfare he thinks will depend, as it has done in the past, on the leaders we choose, and our choice will depend on our capacity to recognise talent and character and use them for the common good Production of luxuries can have little ultimate value "if accompanied by inefficient and vulgar consumption In a true scale of values liberty, security and reasonable leisure stand far higher than mere luxury" Here then, he considers, is good reason for revising our system of education so as to achieve the highest attainable common standard without lessening scope for the exercise of individual talent A difficult programme, but one worth achieving May we hope he will expand this thesis in another book?

Modern Treatment Year Book, 1942

Editor Cecil P G Wakeley, CB, FRCS London Medical Press and Circular Pp 300 12s 6d

This volume, the eighth of its series, like its predecessors is made up of articles selected for republishing because they are important to the general practitioner Though described as a book of treatment, it gives as much space to diagnosis as to therapeutics, sometimes more Practitioners will find it the more useful on this account and will appreciate the essentially practical attitude of most contributors There is some unevenness, the paper on obesity, for example, is divorced from war-time dietetics When advising diet in cases of high blood-pressure it scarcely seems necessary to advise inclusion of principles "known as vitamins" In contrast, clear instructions and guidance are given in Manson-Bahr's treatment of dysentery, E Fletcher's account of arthritis, and Macnab's description of transfusion in war injuries About 20 articles are devoted to general medicine, 14 to special aspects of war medicine or surgery, 11 to general and orthopædic surgery Some of the operative details given by Maingot on the surgical treatment of irremovable duodenal ulcer seem slightly out of place in a volume for general practitioners As a useful refresher course in recent methods this volume will be welcome

Black's Medical Dictionary

(17th ed) J D Comrie, MD Edin, FRCPE London Adam and Charles Black Pp 1006 21s

A dictionary which has had seventeen editions in 36 years needs no introduction, and it only remains to note briefly the newer features A section on air-raid casualties is quite properly dogmatic, and there is a short but comprehensive account of the various sulphonamides The section on anæsthetics, however, hardly gives an adequate account of present methods and apparatus There are some brief references to a few forms of industrial disability, but industrial disease is not dealt with as a whole Yet the positive merits of "Black" are so outstanding that such omissions may well be forgiven

THE LANCET

LONDON SATURDAY, OCTOBER 24, 1942

NEONATAL MORTALITY IN THE USA

In the United States D A D'Esopo and A A Marchetti[1] have set out to obtain accurate information about the causes of 1000 fœtal and neonatal deaths over a period of six years at the New York Lying-in Hospital and the Sloane Hospital for Women Their investigation is particularly valuable because an autopsy was obtained in 893 cases They frankly face the multiplicity of factors involved in a single case, and carefully review all clinical and pathological data before determining the primary cause of death The gross fœtal and neonatal mortality-rate represented by the 1000 cases was 3 87%, and if previable prematures are excluded the rate becomes 3 52 The first five causes of death listed are asphyxia (198 deaths), prematurity (as a primary cause, 185), congenital abnormalities (141) maceration, cause unknown (130), birth injury (115) In 30 cases no cause of death could be found, and some items make surprising reading, such as 28 instances of erythroblastosis and 21 of hæmorrhagic disease of the newborn The causes of asphyxia are analysed in detail, particularly from the point of view of prevention These two obstetricians believe that the preventive treatment of this condition should begin in utero with a more judicious use of oxygen and ether anæsthesia in cases in which the fœtus begins to show early signs of distress They especially condemn "hurry" in such circumstances with operative interference Premature separation of the placenta and prolapse of the cord as causes of asphyxia appear frequently in their analysis and they urge that better obstetrics might do much to help with these problems, mentioning the dangers of pituitary extract in this connexion In a study of the relation of inhalation analgesia to asphyxia neonatorum C J Lund[2] of Wisconsin has analysed complete records of 1982 deliveries, and has based his conclusions on a careful classification of all infants alive at the onset of labour under the heading "no asphyxia," "mild asphyxia," "moderate asphyxia" and "severe asphyxia," the last group containing the fatalities The results show that when properly administered with due regard for the prevention of anoxæmia the three anæsthetic agents chiefly used in this study—nitrous oxide, ethylene and cyclopropane—do not materially influence the incidence of asphyxia so long as they are used only as analgesics But when they are pushed for the production of anæsthesia there is an increased risk of asphyxia, particularly when the period of administration of cyclopropane is increased More important than the inhalation agents or method actually used were complicating factors such as prematurity and complications of pregnancy and labour It is the summation of effects of which anæsthesia may be the last straw which results in asphyxia, and it is therefore rash to speak of a completely safe obstetric analgesic

Second on the list in the New York series came prematurity, and a recent report from Ann Arbor, Michigan, shows once again what can be done by organised team-work in the infant nursery to improve the survival-rate of immature infants A C Barnes and J R Willson[3] report a fall in mortality for the periods 1932–36 and 1937–41 from 32 5 to 9 5% The chief factors in this success appear to have been better and more nursing care, more and better incubators and a freer use of oxygen

The report brings out the importance of careful temperature recording and of maintaining the humidity of the air breathed by the infant at 50 to 60% Careful protection from infection is fundamental and so is the use of breast milk for feeding; at Ann Arbor they use dilute unsweetened condensed milk as an alternative The New York workers also emphasise the value of adequate pædiatric organisation for the saving of premature babies, particularly during the first twenty-four hours of life. The Michigan programme includes vitamin K in the first 2 or 3 days to prevent a prothrombin drop, and a study in Chicago illustrates yet again the multiplicity of factors in neonatal troubles, for J E Fitzgerald and A Webster[4] show that the administration of certain barbiturates (sodium pentobarbital or sodium amyl bromoallyl barbiturate) as analgesics depresses the blood prothrombin levels in mother and child When these drugs are used it seems specially desirable to give vitamin K to the mother during labour It does not follow that barbiturates are a direct factor in promoting neonatal hæmorrhage but they may play some part

PETHIDINE
